### WAR DEPARTMENT, WASHINGTON 25, D. C., 5 OCTOBER, 1943

TM 11-862, Technical Manual for Radio Set SCR-504-A (Direction Finding), is published for the information and guidance of all concerned.

[A. G. 300.7 (25 September 1943).]
BY ORDER OF THE SECRETARY OF WAR:

G. C. MARSHALL,

Chief of Staff.

OFFICIAL:

J. A. ULIO,

Major General,

The Adjutant General.

**DISTRIBUTION:** 

IC 11 (5)

#### **DESTRUCTION NOTICE**

- WHY— To prevent the enemy from using or salvaging this equipment for his benefit.
- WHEN—When ordered by your commander or when you are in immediate danger of capture.
- **HOW** 1. Smash—Use sledges, axes, hand-axes, pick-axes, hammers, crowbars, heavy tools, etc.
  - 2. Cut—Use axes, hand-axes, machete, etc.
  - 3. Burn—Use gasoline, kerosene, flame-throwers, incendiary grenades, etc.
  - 4. Explosives—Use firearms, grenades, TNT, etc.
  - 5. Disposal—Bury in slit-trenches, fox-holes, other holes. Throw in streams. Scatter.

#### USE ANYTHING IMMEDIATELY AVAILABLE FOR DESTRUCTION OF THIS EQUIPMENT

- WHAT—1. Smash—Tubes, meters, controls, switches, batteries, rectifier, sockets, chest, syringe, panels, capacitors, resistors, headsets, and vibrator.
  - 2. Cut—Cords and wiring.
  - 3. Bend and/or break—Loop, sensing antenna, cabinet, and panels.
  - 4. Burn—Sockets, wiring, cords, capacitors, resistors, transformers, wiring diagram, manual, suitcase, chest, and coils.
  - 5. Bury or scatter—All remaining parts.

#### DESTROY EVERYTHING

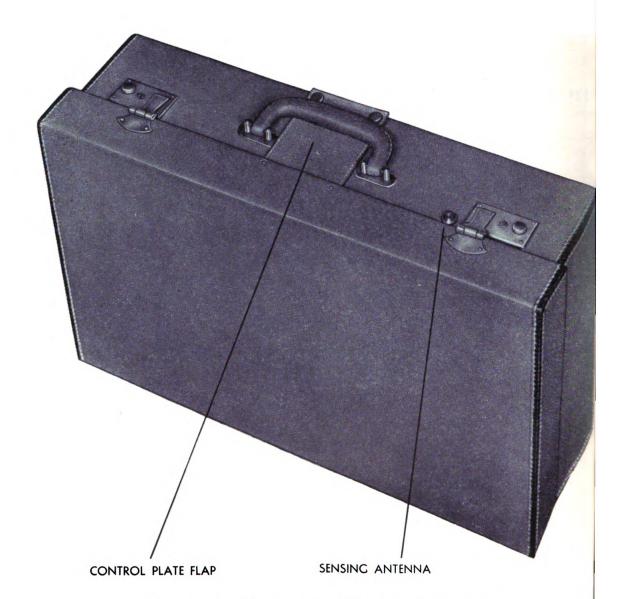

Figure 1. Radio Receiver BC-792-A, Outside View

#### **SECTION I**

#### DESCRIPTION

1. General.—Radio Set SCR-504-A is a portable radio direction finder (d/f) which has a portable Battery Charger PE-128-A and a Case CS-96-A for carrying the PE-128-A and spare parts. The direction finding receiver is called Radio Receiver BC-792-A and it is quite different from anything you've had yet. But it's not entirely unlike the little portable you used to take with you to the football game or on a picnic. Remember how you used to have to turn the little portable in a certain direction to get the best pickup from a given radio station? It's the same with the BC-792-A. The only difference is that with the portable, entertainment was the main thing and you turned your set in such a direction as to get the best results. With the BC-792-A, the entertainment you get is only incidental. It's the way Radio Receiver BC-792-A points that counts, because that tells you the direction of the friendly or enemy transmitter.

In figure 1 you see Radio Receiver BC-792-A as it looks to the ordinary person—just another pigskin suitcase. In figure 2 you see the suitcase open showing the radio set, while in figure 14 you see "yourself" carrying the receiver and operating it as you walk. It's true—you can "direction find"—d/f—as you walk along, or you can set Radio Receiver BC-792-A on the ground, or on a tree stump, and d/f from there.

#### 2. Power Supply.—

a. For Radio Receiver BC-792-A:

1 Battery BB-51 6 volts

.1 amperes

2 Batteries BB-52

72 volts (total) .017 amperes

(The above batteries when new or freshly charged will operate the receiver for 3 to 4 hours.)

b. For Battery Charger PE-128-A:

Vehicular Battery 6 volts 1.2 amperes

Vehicular Battery 12 volts .6 amperes

Par. 3

RADIO SET SCR-504-A

TM 11-862

Digitized by Google

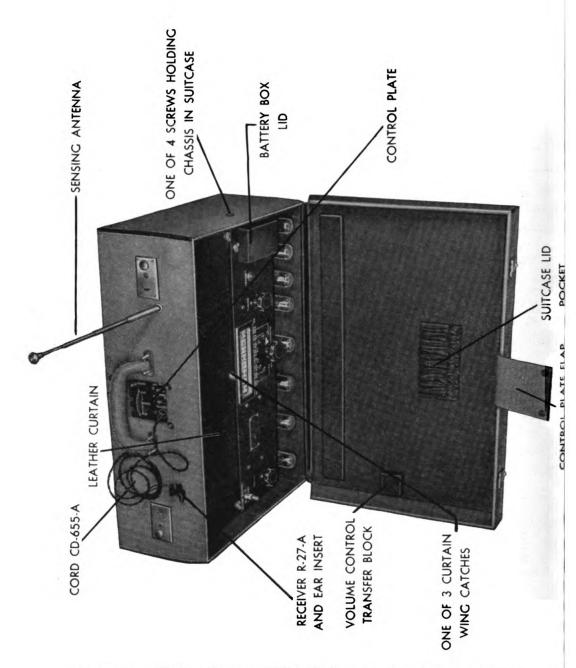

Figure 2. Radio Receiver BC-792-A, with the Suitcase Open Showing Contents, and the Sense Antenna up

4. Radio Receiver BC-792-A (figures 1, 2)—Radio Receiver BC-792-A, housed in a suitcase, is an 8-tube superheterodyne covering a frequency range of from 100 kc to 65 mc. in eight bands. It is designed to receive either continuous-wave or amplitude-modulated signals. A complete set of tubes is installed in Radio Receiver BC-792-A when it reaches you. The tuning dial is calibrated in megacycles. Power supply for Radio Receiver BC-792-A is a set of miniature storage batteries (one 6-volt and two 36-volt) which are housed in an easily-accessible compartment on the receiver panel. The panel VOLUME control is used when the suitcase lid is open; when the lid is closed the VOLUME control on the plate under the carrying handle is used (figure 11). These two controls are electrically independent—the VOLUME CONTROL TRANSFER disengages the inside control and engages the outside control when the id of the suitcase is closed.

Headset HS-34-A, provided with Radio Receiver BC-792-A, is onnected to the HEADSET jacks on the control plate (figure 11). This headset, of the hearing-aid type, uses ear inserts, one to fit each ar. A panel HEADSET jack (figure 10) is provided for connecting conventional headset by means of standard Plug PL-55.

The antenna stage of the receiver uses a single turn loop as a irectional pickup and a collapsible rod antenna as a non-directional ickup. Connection of the rod antenna to the antenna stage is made y pushing the SENSE button on the control plate (figure 11). When he rod antenna and the loop antenna are connected they form the sensing" device which tells you the direction of the transmitter.

5. Battery Charger PE-128-A (figure 3).—Battery Charger E-128-A is designed to operate from either a 6-volt or a 12-volt shicular storage battery. Connections to the supply battery are made y using Cord CD-658-A, which is stored in a compartment inside the ear door. Identification tags on Cord CD-658-A indicate the voltage 1d polarity for connecting it to the supply battery. The SUPPLY vitch on the panel has two functions: a. by moving the key to the p or bottom positions, the charging current is turned on; by moving the key to the middle OFF position the charger is rned off. There is a position-locking mechanism on the switch prevent its being jarred to the OFF position. Opening the cover the top of the charger exposes the receptacles for the miniature prage batteries. One set (one BB-51 and two BB-52's) of these

Figure 3. Battery Charger PE-128-A, Front View, Top Closed

atteries is charged at a time. Meters on the panel indicate the charging currents and voltages of each battery as the METER RANGE witch is turned. The A-CURRENT and B-CURRENT controls on the anel adjust the charging rates. Condition of the batteries may be hecked by pushing the BATTERY LOAD TEST button. The charger protected from damage by fuses in the main circuits. Each of the tree fuse blocks contains one active (connected in series with the ircuit) and one spare fuse. To inspect and replace fuses, open the ear door (figure 23).

6. Case CS-96-A (figures 4, 6).—Case CS-96-A is a plywood use which houses Battery Charger PE-128-A and accessories. The ase has metal-reinforced corners. The rubber strip on which the inged lid rests forms a water-tight seal when the draw bolts are osed. A hinge hasp suitable for padlocking is provided.

The interior of the case is divided into compartments for the ontents. A removable tray in the upper right-hand side of the case figure 4) is designed for the six miniature storage batteries. The nallest compartment in the tray is for the hypodermic syringe hen it is not packed away in its transit compartment, below the ay. The tray and the compartments below it are coated with an eid-resisting enamel. On the under side of the lid is a list of connts, together with a chart showing how the contents are placed in the case (figure 5). These accessories and spares are in Case CS-96-A:

- a. Headset HS-34-A.—This headset consists of Cord CD-655-A and Receiver R-27-A. The cord is long enough to put through the coat eeve of the operator, and provide sufficient slack at head and hand allow for easy manipulation. The two conductors are tied together ther close to the tips so they may be easily inserted into the head-t jacks. Receiver R-27-A is of the hearing-aid type, and is provided ith a projection to which you snap the ear insert described below.
- b. Ear Insert.—Made of black, hard rubber shaped to fit the r, ear inserts are supplied in two types—one for the left ear and one r the right. You attach the insert to Receiver R-27-A by fitting the ojection on the receiver to the larger hole on one side of the earsert, then snap them together with a little finger pressure.

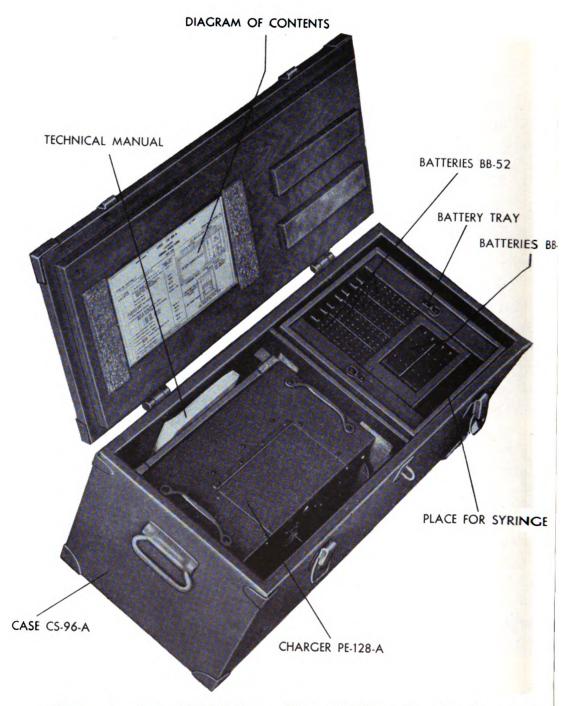

Figure 4. Case CS-96-A, Front View, Lid Open Showing Contents

Generated on 2015-10-06 14:41 GMT / http://hdl.handle.net/2027/uc1.b3243879 Public Domain, Google-digitized / http://www.hathitrust.org/access\_use#pd-google

- c. Tube Kit.—Each tube kit contains a complete set of tubes for Radio Receiver BC-792-A, consisting of the following:
  - 1 1LB4
  - 1 1LH4/VT-177
  - 1 1LC6/VT-178
  - 5 1LN5/VT-179
- d. Battery BB-51.—Used as the "A" battery for Radio Receiver BC-792-A, Battery BB-51 is a miniature storage battery which furnishes 6 volts. It is packed in a state of "dry charge" and you must fill it with acid before using (see paragraph 8b for details).
- e. Battery BB-52.—This miniature storage battery furnishes 36 volts. Two are connected in series and comprise the "B" supply for Radio Receiver BC-792-A. Battery BB-52 also is packed in a state of "dry charge" and must be filled with acid before using (see paragraph 8c for details).
- f. Hypodermic Syringe.—You use the hypodermic syringe for filling the batteries. It consists of two glass parts: a plunger and a barrel, graduated to 5cc. The scale in cubic centimeters (abbreviated: cc) on the graduated barrel indicates the amount of acid you draw into the syringe. For use and care of the syringe see paragraphs 8a, b, c, d.
- g. Hypodermic Needle.—The hypodermic needle is made of rustless steel and fits on the small end of the barrel of the syringe. Together the needle and syringe are used for filling the miniature patteries.
- h. Acid Bottle.—The 16-oz. bottle, packed empty, is large enough to hold a supply of acid to fill and replenish several sets of batteries.
- i. Rubber Stopper.—The rubber stopper serves the two-fold purpose of (1) closing the bottle and (2) allowing the hypodermic tyringe to be filled when the bottle is nearly empty. Pierce the center of the stopper with the needle and the bottle may then be placed on its side (or even upside down), if necessary, to submerge the end of the needle.
- j. Blotters.—Blotters are used for removing excess acid from he miniature batteries while they are charging or being filled. See paragraph 8e for instructions on how to blot the batteries without hort-circuiting the cells.

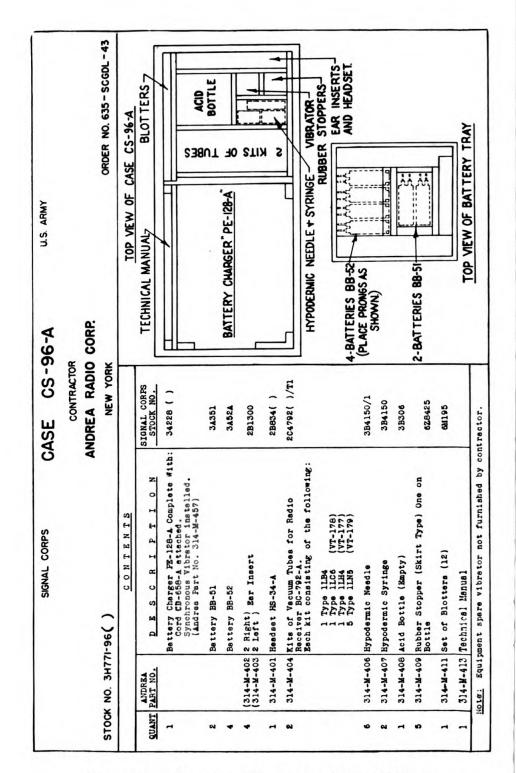

Figure 5. Diagram of Contents of Case CS-96-A

#### **SECTION II**

#### INSTALLATION AND OPERATION

- 7. Unpacking.— To unpack Radio Set SCR-504-A you set the packing case on its bottom in a place where you have plenty of elbow room to work. After removing the boards on top, using a nail puller to pry them loose, you will find two cartons. Remove the BC-792-A carton first by pulling it straight up. Then remove the other.
- a. Set the BC-792-A carton on its bottom. Use a knife to slit the paper seal holding the flaps on the top. Then remove the folded cardboard "accordion" in the top of the box. Now grasp the handle of the suitcase with one hand, hold the box down with the other, and pull the suitcase straight up and out of the box. This suitcase contains Radio Receiver BC-792-A.
- b. Open the other carton and remove Case CS-96-A. Set the wood case on its bottom and open the three latches holding the cover. Swing back the lid. The metal box is Battery Charger PE-128-A. Grasp the handles and pull it straight up. Remove the battery tray in order to get at the acid bottle and other items required to fill the batteries.
- (1) Remove one set of batteries from the tray. A set of batteries contains: one "A" battery and two "B" batteries, labeled BB-51 and BB-52, respectively. The "A" Batteries (BB-51) have six pin holes on top while the "B" Batteries (BB-52) have a large number of pin holes on top.
- (2) Remove the acid bottle and fill it with sulfuric acid (1.280 specific gravity) from the container which is shipped with the batteries. If this container is missing or broken, have the acid bottle filled at your supply base using acid for vehicular batteries. Caution: Sulfuric acid is very corrosive to metal and destructive to fabrics. Don't let it get on equipment or clothing. Be careful.
- 8. Filling the Batteries.—Miniature storage batteries BB-51 and BB-52 (figure 7) are charged, but dry, and before they can be used for generating current their cells must be filled with sulfuric acid. Before filling the hypodermic syringe with acid to put in the cells, however, the empty syringe should be used to pierce the seals inside the cell holes of each battery (6 for BB-51, 36 for BB-52). Push the needle into the cell hole as far as it will go with a light finger-pressure.

Figure 6. Case CS-96-A and Contents

#### a. To Fill Hypodermic Syringe:

TM 11-862

- (1) Push plunger completely into barrel.
- (2) Push needle through center of rubber stopper of acid bottle until point of needle is immersed in acid. If needle does not reach acid, lay bottle on its side or turn it upside down (figure 8a).
- (3) Slowly pull out plunger—acid will be drawn into barrel through needle.
- (4) When acid reaches 5 cc level, stop pulling plunger and withdraw needle from stopper.

#### b. To Fill Battery BB-51:

- (1) Insert needle into either of the previously-punctured holes numbered 1 of cell #1 (figure 7).
- (2) Slowly force the acid out of the syringe by pushing the plunger with the thumb.
- (3) Approximately 6 cc of sulfuric acid are needed to fill each cell in the BB-51.
- (a) If the air can't get out of the battery fast enough a small pool of acid will form around the hole being filled, even before the cell is full. Just wait a minute, it will soak in.
- (b) When the cell is filled, air bubbles stop coming out and both holes of the cell show liquid at rest.
- (c) If acid soaks into one cell slowly and tends to run over, go to the next cell and give the other cell time to settle down.

#### (4) DON'TS

- (a) Don't let the acid cover the top of the battery from one hole to the next because this shorts the cells, wastes the current, and will eventually cause the battery to burn up.
- (b) Don't rush the job. Be patient. Rapping the battery gently an a hard surface with an up-and-down motion helps the acid to settle down faster. Gently tapping it with the finger also helps. Slowly noving the hypodermic needle up and down will help, too, but if you to this, be careful you don't break the needle or injure the battery.

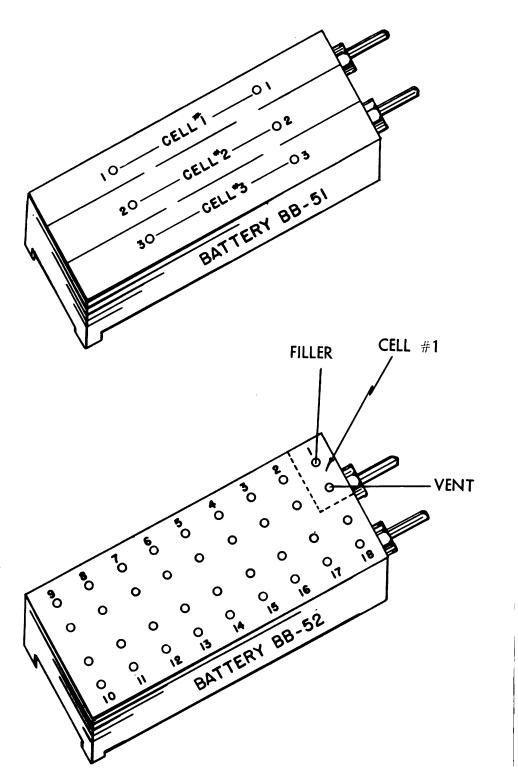

Figure 7. Miniature Storage Batteries BB-51 and BB-52

#### c. To Fill Batteries BB-52:

- (1) Insert needle into previously-punctured cell #1 using the hole of the cell nearest the edge of the battery (the two lines of holes toward the center of the battery are vent holes). About 1 cc. of acid is needed to fill each cell. (See figure 8b.)
- (2) Next fill cell #3 and continue filling the cells in this order, i.e., #3, #5, #7, etc. It is better to give each of these cells a small "shot" at a time and not try to fill each completely, at once.
- (3) When all the odd-numbered cells (#1, #3, #5, #7, etc.) are filled, blot up the extra acid and fill cells #2, #4, #6, etc. See paragraph 8e for tips on the safe way to blot up the acid.
- (4) After blotting up any excess acid on the top of the battery, put it aside to await test.

#### (5) DON'TS

- (a) Don't let puddles of acid run over the top of the battery from one cell to another because this shorts the cells, wastes the current, and burns up the battery.
- (b) Don't rush the job. Be patient. Rapping the battery gently on a hard surface with an up-and-down motion helps the acid to settle down faster. Gently tapping it with the finger also helps. Slowly moving the hypodermic needle up and down will help too; but if you do this, be careful not to break the needle or injure the battery.
  - (6) Fill the other BB-52 by the same method.
- d. Immediately after finishing with the syringe and needle, wash them thoroughly with clean water. Fill the syringe several times and squirt the water through the needle. Remove the needle from the syringe and let the parts dry.
- e. Blotting.—The correct way to "blot" the excess acid from the batteries is to tear a small piece from one of the blotters and use the edge of the blotter, not the flat surface. Then maneuver the piece of blotter, edge up, from hole to hole, being careful not to connect two holes with the blotter (figure 16). The blotter soaked with acid is a good conductor and will short-circuit the cells if you aren't careful.

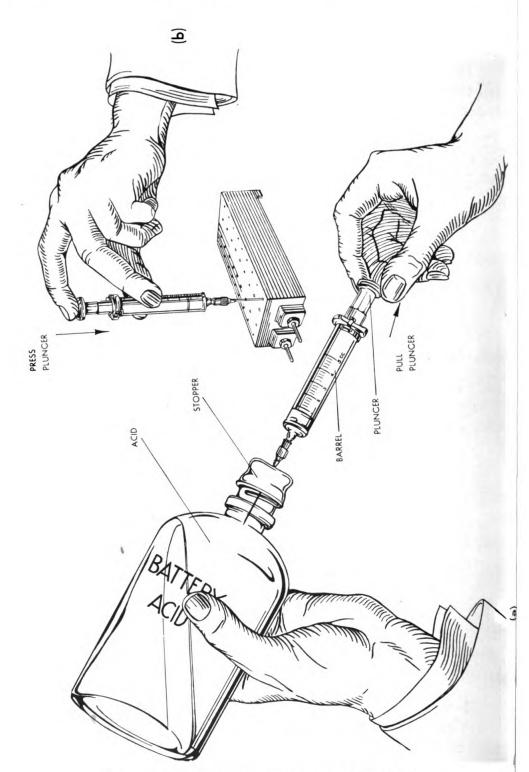

Figure 8. Filling the Syringe and Batteries

- 9. Testing the Batteries.—The BB-51 and BB-52 when filled for the first time do not require charging. Before they are put into Radio Receiver BC-792-A for use, however, they should be checked by measuring their terminal voltage under load. This you can do on the charger:
- a. Open the latch on the front panel over the METER RANGE and raise the battery compartment lid (figures 3, 9).
- b. Plug in the BB-51 as indicated by the markings next to the jacks.
  - c. Throw METER RANGE to position marked "A".
- (1) Read voltage on red-marked "A" scale of meter labeled VOLTS. It should show at least 6 volts and may be as high as 6.5 volts.
- (2) Now push button marked BATTERY LOAD TEST, and read the volts again. It, too, should show at least 6 volts and may be slightly higher. If the BATTERY LOAD TEST voltage is less than 6 volts, you have not filled one or more of the cells completely, or else the battery isn't fully charged. First check the cells by adding more acid where needed; then if necessary, recharge (see paragraph 17).

The difference between the readings obtained in (1) and (2) is:

- (1) Shows the voltage when the battery has no load on it, i.e., no current is being drawn from the battery.
- (2) Shows the voltage when the battery is connected to a load equal to that provided by Radio Receiver BC-792-A.
- d. Plug in both BB-52 batteries in the jacks marked for these batteries. (All three batteries may be plugged in at the same time.)
  - e. Throw METER RANGE to first position marked "B".
- (1) Read voltage on black-marked "B" scale of meter labeled VOLTS. It should show at least 36 volts and may be as high as 40 volts. If no voltage is measured, or the value is extremely low, one or more of the cells probably is not filled with acid, or else the battery isn't fully charged. Check up before going any further.

Figure 9. Battery Charger PE-128-A, Front View, Top Open, Batteries in Place

- f. Throw METER RANGE to the other "B" position and read voltage again for the second BB-52.
- g. If both batteries have measured at least 36 volts each, proceed with the load test for the "B" batteries. CAUTION: BOTH BB-52 BATTERIES MUST BE PLUGGED IN WHEN THE LOAD TEST IS MADE. Since these batteries are connected in series, the load is not applied if only one is plugged in. If only one is plugged in, all that registers is the no-load voltage, which does not mean much. You make the load test as follows:
  - (1) Throw METER RANGE to first B position.
  - (2) Push BATTERY LOAD TEST button and read voltmeter.
  - (3) Throw METER RANGE to other B position.
- (4) Push BATTERY LOAD TEST button and read voltmeter again.
  - (5) Both batteries should measure at least 36 volts under load.
- h. If either battery load voltage is less than 36 volts, one or more of the cells has insufficient acid or the battery isn't fully charged. Check cells by adding acid as needed and repeat load voltage test. If necessary, recharge the batteries (see paragraph 17).
- 10. Preparing Radio Receiver BC-792-A for Use (figure 2).—To make Radio Receiver BC-792-A work do the following:
- a. Place the suitcase, handle up, with the lid next to you. Unlock the two latches with key you find tied to handle (don't leave keys here—they'll get lost), and push the brass buttons toward ends of the suitcase. (Don't leave your knuckles in the path of the latch as the snap spring opens the latches with considerable force.) Unfasten leather flap under suitcase handle by pulling snap buttons, and open lid of suitcase.
- b. Turn wing fastener at top of battery compartment door at right side of panel and open battery compartment door. Push BB-51 and two BB-52 batteries into compartments indicated by the markings (figure 10). Make sure to push them in as far as they'll go. Close and fasten battery compartment door.
- c. Remove Headset HS-34-A from the small pocket on the suit-case cover and plug the tips of its Cord CD-655-A into the tip jacks marked HEADSET on the control plate under the suitcase handle.

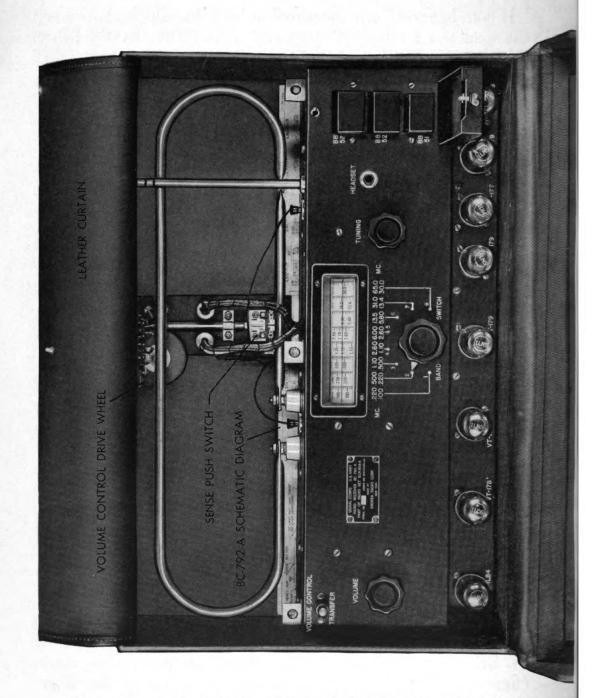

Figure 10. Radio Receiver BC-792-A, Suitcase Open, Curtain Up, Showing Loop Antenna, Battery Box Open Showing Batteries

- d. Pull out the collapsible rod antenna as far as it will go by grasping the small brass button on the top of the suitcase near the right-hand latch. When the antenna is completely extended, five sections are visible.
  - e. The receiver is now ready for operation.

#### 11. Tuning in Radio Receiver BC-792-A.—

- a. Throw to ON, POWER switch which is mounted on control plate shown in figure 11.
- b. Select frequency band by turning BAND SWITCH knob, front of receiver panel (figure 10).
  - c. Insert the earphone in the right ear (figure 12) as follows:
- (1) Hold the earphone with the thumb and index finger so that the "wing" on the eartip is at your index finger tip pointing away from you, as shown in figure 12.
- (2) Without changing your hold on the earphone, catch the "wing" in the front rim of your ear.
- (3) Slide the wing down the rim and at the same time gently press the "horn" projection into your ear.
- (4) Lead Cord CD-655-A from the phone around your ear, between it and your head. Normally Cord CD-655-A will tuck in under your shirt collar (figure 12), run along your arm under your shirt sleeve, out at the wrist and into the tip jacks marked HEADSET on the control plate under the suitcase handle. Of course if you aren't on a "snooping job" no need exists for concealing the headset in this manner and you can operate with any low-impedance headset plugged into JK-34-A on the front panel at the place marked HEAD-SET.
- d. Turn VOLUME knob clockwise until you hear some noise in the headset.
- e. Tune in the desired signal with TUNING control. The signal frequency is indicated in megacycles on the drum dial above the BAND SWITCH markings (figure 10).
- f. You are now ready to locate the position of the transmitter from which the signal comes.

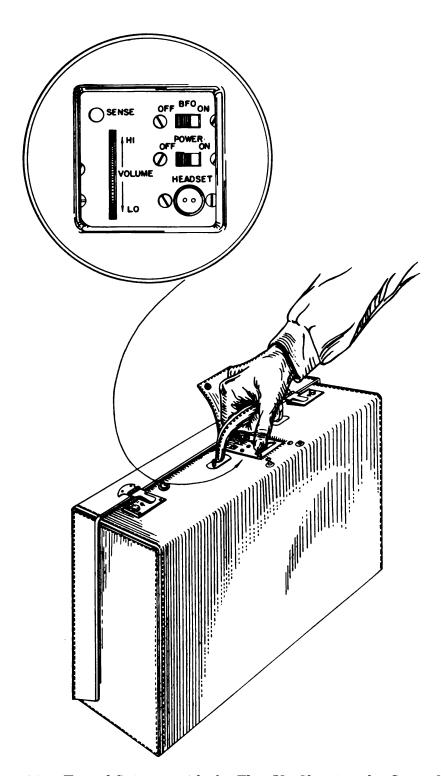

Figure 11. Top of Suitcase with the Flap Up Showing the Control Plate

#### 12. Finding the Path of Signal for all Bands.—

M 11-862

- a. Turn rim of VOLUME control on control plate under handle o LO positon.
- b. Close lid of suitcase making sure you snap both latches and eave leather flap open—don't tuck it under the handle (see figure 11).
- c. Turn VOLUME control towards "HI" until you get a comfortable signal in your ear.
- d. Hold the suitcase by the handle at your right side in normal fashion and slowly turn on the spot where you are standing. As you turn slowly through a complete circle you hear the signal volume changing.
- e. In the circle you make, as you turn with the suitcase, there will be two positions in which the signal is weakest. These positions are called the "nulls". (Figures 13, 14, 18.)
- (1) Each of these "null" (weak signal) positions of the suitcase indicates that the suitcase is broadside to the path of the signal. But you can't tell yet whether the signal's coming or going along this path—that is, whether the transmitter is at "Punch" or "Judy", as shown in figure 13.
- (2) If the signal gets too weak for you to find the exact positions where the signal is weakest, turn up the VOLUME control.

#### 13. Finding the Direction of Signal or "Sensing" for Bands 1 to 6.—

- a. Set the VOLUME control so that reception in the positions where the signal is loudest does not overload the receiver. The receiver is overloaded when the signal sounds mushy or distorted.
- b. Hold the suitcase at your right side WITH THE SENSE ANTENNA END FORWARD. Put your thumb on the SENSE button and push it down several times as you slowly turn in a complete circle on one spot. Each time you push down the button, make a mental note of what happens to the signal; that is, does it get louder or weaker. Keep on turning in the circle until you know in which positions of the suitcase the signal gets louder or weaker when you push the SENSE button. For the suitcase positions in which the

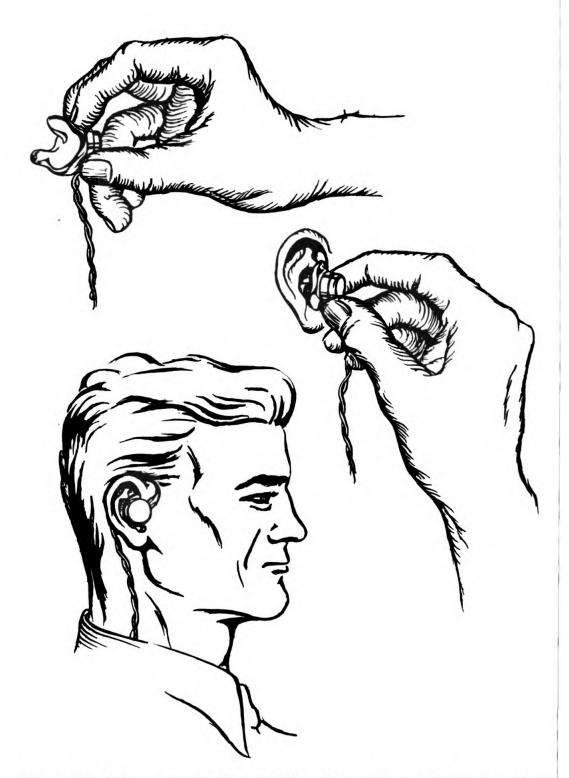

Figure 12. Three Steps for Inserting Ear-piece of Headset HS-34-A in the Ear

Generated on 2015-10-06 19:35 GMT / http://hdl.handle.net/2027/uc1.b3243879

ignal gets louder, you are facing in the general direction toward he transmitter. For the positions in which the signal gets weaker, you are facing in the general direction away from the transmitter. Since you know both the general direction toward the transmitter and the exact path of the signal (from paragraph 12), you now can combine this information to get the exact direction of the transmitter.

Suppose you happened to pick a spot for the receiver between wo transmitters: "Punch" and "Judy", as shown in figure 13. The 'null" positions of the suitcase for a signal coming from either ransmitter would be at 3 and 7, thereby leaving you in doubt from which the signal comes. However, when you make the "Sensing Observations" (figure 13) for "Punch" you find them to be different rom those for "Judy". For example, if "Punch" is radiating, the ignal gets weaker when SENSE is pushed as you turn through positions 4, 5 and 6; whereas if "Judy" is radiating the signal gets weaker when SENSE is pushed as you turn through positions 8, 1 and 2. Note that in both cases the sense antenna end (indicated by he black dot in figure 13) of the suitcase, points away from the adiating transmitter concerned.

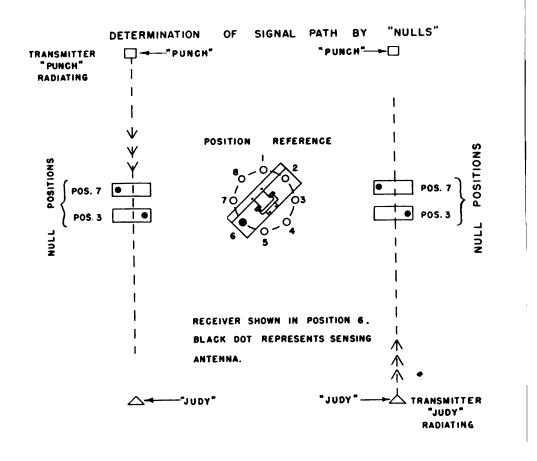

The positions of the suitcase relative to the transmitter are corectly shown in figure 15. Use the sense antenna as a marker.

c. Check the exact path of the signal again by observing the broadside position for the weakest signal without pushing the SENSE outton. Never take a bearing on Sense. The Sense null position is often off by 15 or 20 degrees. Use the Sense only to "resolve the 180 legree ambiguity". This latter is a technical term which means to ind out whether you're "coming or going."

Note: Bands 7 and 8 are not provided with sensing ciruits.

- 14. Beat-Frequency Oscillator (BFO).—a. In case the signal of a transmitter you want to locate is using voice, tone, or telegraph nodulation only intermittently or not at all, you can make an audible thistle or beat by using the beat-frequency oscillator.
- b. Throw the BFO switch on control plate under suitcase handle on ON (figure 11).

#### SENSING OBSERVATIONS

#### SIGNAL FROM 'PUNCH' SIGNAL FROM 'JUDY' WHEN SENSE IS PUSHED WHEN SENSE IS PUSHED Position 1 Signal Gets Louder Signal Gets Weaker Position 1 Position 2 Signal Gets Louder Position 2 Signal Gets Weaker Position 3 Signal Gets Louder Position 3 Signal Gets Louder Position 4 Signal Gets Weaker Position 4 Signal Gets Louder Position 5 Signal Gets Weaker Position 5 Signal Gets Louder Signal Gets Weaker Signal Gets Louder Position 6 Position 6 Signal Gets Louder Position 7 Signal Gets Louder Position 7 Position 8 Signal Gets Louder Position 8 Signal Gets Weaker

Figure 13. Determination of the Direction From Which the Received Signal Comes

- c. Retune the receiver slightly with TUNING knob if you want o change the pitch to a higher or lower note. If the noise is loud and the signal is weak, raising the pitch helps to cut through the noise.
- d. Very weak signals can often be picked up if the b-f oscillator is turned on when "hunting" for signals which might otherwise be bassed over if TUNING knob is turned too fast.
- e. A lot can be gained from using the b-f oscillator. Get acquainted with it and see what it does for you.
- 15. Technique for Direction-Finding Under Difficult Conditions.—a. Location.—There are certain difficult locations which you must learn to recognize by what you see and by how the direction finder works.
- (1) When you're inside or even near buildings having metal peams or roofs you can't rely on the indications of direction you get from the direction finder. The same is true if you are near metal pridges, fences, or transmission lines for power, telegraph, etc. You'll find by experience how these structures give you a "wrong steer" when you're near them. So stay on "the beam" you found pefore approaching them and after getting away you can get back on "the beam" again with confidence.
- (2) If the terrain is very rough and cut up with ravines, always out more trust in the bearings you take along the flat sections or at east the more elevated spots.

The effect of these difficult locations on the direction finder is raried. Sometimes the "nulls" will not be sharp, which of course will be noticed. What is worse, sometimes the "nulls" occur in the wrong lirection. This is bad because you won't know the "null" is in the wrong direction unless you have a previous bearing to go by. Various effects on the sensing performance are also possible when you are n these difficult locations, such as insufficient change in signal or even a misleading change. The safe guide is to take bearings often. The average probably will be right. Get to know your set like you do your watch.

b. Weak Signals.—There will be times when you are in a ocation that has none of the obstacles described above, yet the

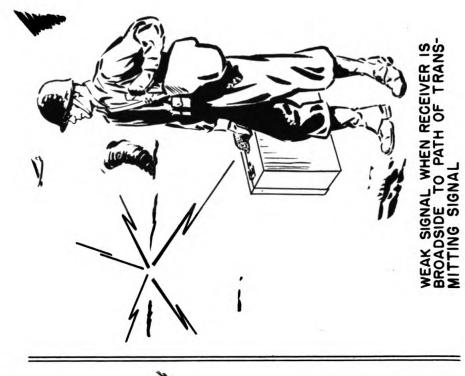

Figure 14. Null and Maximum Positions of Radio Receiver BC-792-A
With Respect to a Transmitter

Generated on 2015-10-06 19:35 GMT / http://hdl.handle.net/2027/uc1.b3243879 Public Domain, Google-digitized / http://www.hathitrust.org/access\_use#pd-google signal you are trying to locate may be weak and almost drowned out by noise. There are several ways to help yourself get a bearing under this condition.

- (1) Reduce the VOLUME to that point at which you can hear the signal most clearly over the noise.
- (2) Use the changes in noise loudness as you rotate the receiver the same way as you normally use the signal.
- (3) Use the BFO as explained in paragraph 14. You now make use of the changes in "whistle" loudness as you rotate the receiver.
- c. "Night Effect".—In frequency bands 4 to 8 you are sometimes going to be up against what is broadly known as "Night Effect." During sunrise and sunset periods the radio waves behave differently. Sometimes they go completely "haywire" and this effect will be particularly troublesome if you are many miles away from the station. One of the earmarks of "Night Effect" is fading of the signal—that is, the signal goes up and down in volume even though you are not moving the receiver nor any controls. Unfortunately there is nothing you can do about "Night Effect" except to be on your guard not to be fooled by wrong bearings. Remember also that sometimes "Night Effect" will not be accompanied by fading but may cause broad nulls which will give false bearings. The only remedy is to know your set so well you can tell when it's "lying" to you. Use your set often; get thoroughly acquainted with it. Then, inless you get mixed up in a barbed wire entanglement, hide yourself under a railroad bridge, walk up the middle of a river, get inside a tank, or land in some other poor situation, the BC-792-A probably will tell you the truth in broad daylight or in the deep larkness of night. It's only when day is changing to night and night is changing to day that you get into real trouble.
- 16. Symptoms of Run-Down Batteries.—As the "A" (BB-51) and "B" batteries (BB-52) in the receiver approach the end of their charge you will notice a decrease in sensitivity by:
  - a. Having continually to increase VOLUME.
  - b. The falling off of noise at full VOLUME.

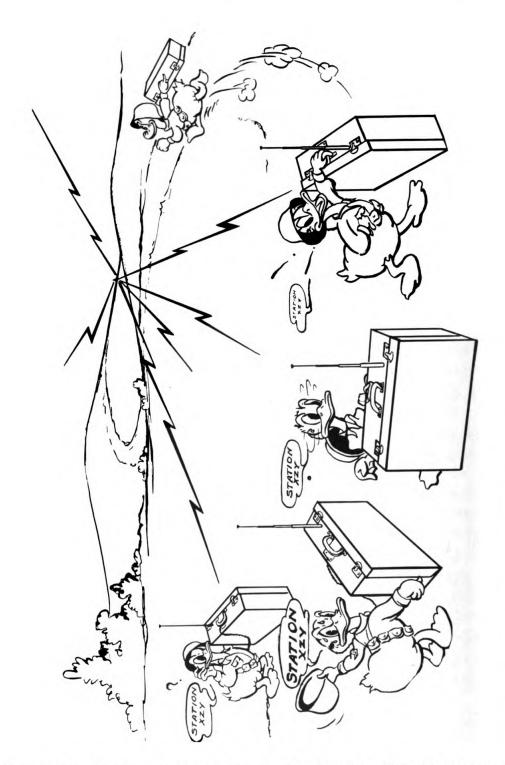

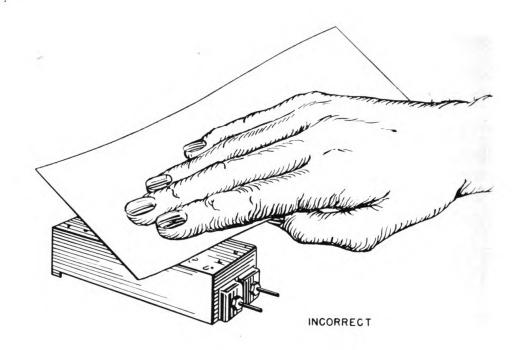

Figure 15. Sensing Positions of Radio Receiver BC-792-A With Respect to a Transmitter, "Donald Duck Finds the Sense"

This period of "dying" does not last more than 5 to 15 minutes and "sudden death" follows. There is no doubt about this, the set stops completely. Then:

Throw POWER switch to OFF to prevent further drain on the batteries until they are removed for charging.

- 17. Operation of Battery Charger PE-128-A (figure 9).— To operate Battery Charger PE-128-A a vehicular storage battery of either 6 or 12 volts is needed for a supply. If no separate battery is available, connection may be made to one installed in a vehicle (see figure 17). If this is necessary, remember that the terminal roltage of the vehicular battery rises considerably when the motor is running and, consequently, you must readjust the A-CURRENT and B-CURRENT controls to restore the currents to the proper values.
  - a. To use the Battery Charger PE-128-A, do the following:
  - (1) Throw SUPPLY switch to OFF.
  - (2) Turn A-CURRENT and B-CURRENT controls to LOW.
- (3) Remove Cord CD-658-A from compartment at rear of charger (figure 23).
- (4) Connect clip marked (—) to negative or minus side of rehicular battery. CAUTION: If you get these battery connections reversed you probably will blow the primary circuit itse in the PE-128-A.
- (5) Connect clip on white wire marked + 6 to + 6 volts on the ehicular battery. The red wire is not used unless you connect to a 2-volt battery (figure 17).
- (6) If a 12-volt battery is used instead of a 6-volt, connect the ed wire marked + 12 to + 12 volts on the vehicular battery. The vhite wire is then not used.
- (7) Plug the BB-51 and the two BB-52 batteries into the proper eceptacles of the battery compartment. Leave the lid open.
- (8) Throw SUPPLY switch to the position corresponding to he supply voltage you are using. This is important.

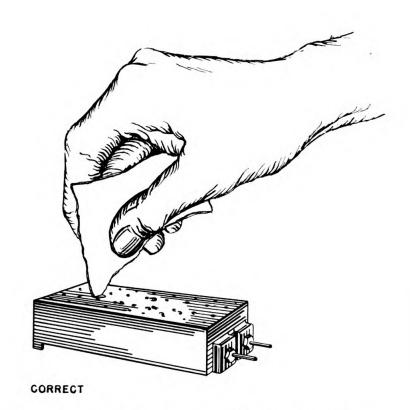

Figure 16. Right and Wrong Way of Blotting Batteries

- (9) Throw METER RANGE switch to "A".
- (10) Adjust "A" battery (BB-51) current (by turning the A-CURRENT control) to 100 milliamperes, which you read on red scale of meter.
  - (11) Throw METER RANGE switch to either "B" position.
- (12) Adjust "B" battery (BB-52) current (by turning the B-CURRENT knob) to 15 milliamperes, which you read on black scale of the meter.
- b. Choice of Charging Rate.—In choosing the charging rate remember that it is better for the batteries if you charge them slowly (low milliamperes). If you have about 8 hours in which to charge them use the slow rate.
  - (1) Slow Rate.—

	BB-51	<b>BB-52</b>
5 Hours at:	100 ma	15 ma
Then about 3 Hours at:	50 ma	8 ma

(2) Fast Rate.—

If you can't take 8 hours, use the fast rate:

	BB-51	<b>BB-52</b>
5 to 6 Hours at:	160 ma	20 ma

(3) Trickle Rate.—If you're not going to need the batteries for a day or two, use the slowest rate, called "trickle". Also use "trickle" to keep charged batteries from running down when they're standing idle.

	BB-51	BB-52
Continuously at:	30 ma	8 ma

c. Blotting Overflow.—While batteries are charging, acid comes out of the holes. You must continually remove this acid with strips of blotter. (See figure 16.) Don't lay a blotter over the holes because the wet blotter short circuits the cells of the battery. If a high charging rate is used, do not leave the batteries alone very long or the acid will completely cover the top, waste the current, and damage the battery.

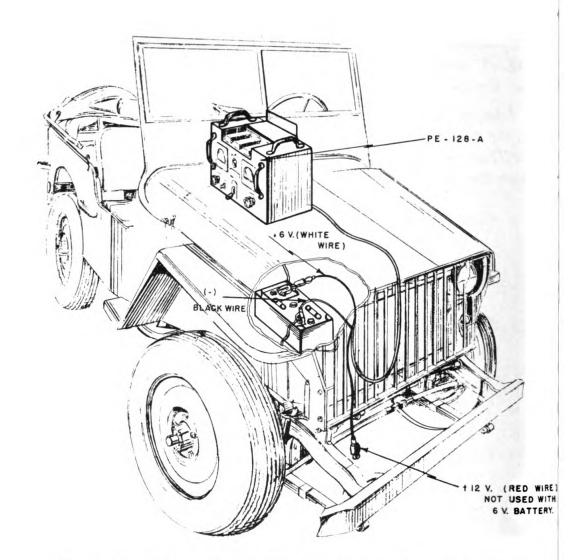

Figure 17. Battery Charger PE-128-A Connected to "Jeep" Battery

Note: Never close the battery compartment lid while charging, unless you want to get blown sky high. (When batteries charge they give off hydrogen which accumulates when lid is closed. The least spark will set it off and you'll suddenly get a face full of acid, get blown off your perch, or both.)

- d. Addition of Acid.—Before the charging has progressed very far, most of the cells will overflow. Then you should add acid to any cells that show no signs of overflowing.
- e. Testing Batteries.—After you have charged the batteries, make sure they are in good shape by testing them as described in paragraph 9. You don't have to disconnect the charger or turn it off when you make this test, since the BATTERY LOAD TEST switch takes care of this.
- f. To get maximum life out of each charge let the batteries sit and bubble several hours after charging, blotting up the acid which bubbles out. Then take your hypodermic syringe and acid bottle, and refill the batteries with acid, letting the batteries stand a few hours, if necessary, before putting them in the BC-792-A. The reason acid bubbles out of the batteries is not that there is too much acid, but that gas gets caught in the tiny cells and blows the liquid out. For maximum life, each cell should be full of acid and the bubbling should have stopped before the battery is put in the BC-792-A. Batteries will stay charged about three days when sitting idle. For maximum life and usefulness batteries should be trickle-charged each night.
- g. Care of Batteries.—The following rules should be observed in order to get the maximum service from miniature storage batteries:—

### DON'TS

- (1) DON'T let a dead battery stand without charging.
- (2) DON'T let the acid get low.
- (3) DON'T let a puddle of acid cover the top of batteries.
- (4) DON'T use a high charging rate unless it's absolutely necessary.
- (5) DON'T leave the batteries in the sun or in the rain.

(6) DON'T fill batteries until they are actually needed in service. After they are filled they require attention practically every day.

#### DO'S

- (1) Always put batteries, once they have been filled and when not in service, on "trickle charge" even if they are fully charged at the time.
- (2) Keep contact pins clean and shiny.
- (3) Always shut off the POWER switch to the receiver when you're not using it. There is no need to keep the set "warmed up".

After you have had 30 to 40 hours of total service from the batteries in the receiver, you'll find the batteries won't charge up any more nor will they last very long in the receiver after charging. This means the batteries are worn out and must be turned in for replacement or thrown away. The life of the battery depends on the care you give it—it may last less than 30 hours or more than 40 hours.

- h. Care of Battery Charger PE-128-A.—Always be very careful in connecting Cord CD-658-A to the vehicular battery. Watch the following:
  - (1) Black lead goes to minus side.
  - (2) White lead goes to + 6 volts.
- (3) Red lead goes to + 12 volts. (NEVER connect white lead to + 12 volts. If you don't watch these connections you will blow the 4-amp primary fuse.)

ALWAYS turn A and B-CURRENT controls to LOW before turning on the charger. If you don't do this, you'll blow the "A" and "B" fuse. (If any fuses blow, see paragraph 23 on replace ment.) Turning the controls to LOW will prevent an excess of charging current when you throw the SUPPLY switch. The safest practice is always to throw the CURRENT control to LOW the moment you are through with the charger. Then it's ready for use the next day.

#### **SECTION III**

#### FUNCTIONING OF PARTS

"There's no very good substitute for knowing how."

18. Radio Receiver BC-792-A.—Radio Receiver BC-792-A is, except for its antenna system, just like any other portable radio receiver which covers the same frequency range. Because of this similarity, functioning of the direction finder will be explained in two parts. Paragraph 18a will explain the equipment in terms of an ordinary radio receiver; paragraph 19 will explain the directional characteristics of the receiver's antennas.

## a. Receiver Circuits (figure 36).—

- (1) The antenna transformers (81-87) of bands 1 to 7, couple the low impedance loop (121) to the signal grid of the R-F tube (118-1). The low-inductance primaries of these transformers are switched by sections F and H of the band switch (132). The primaries of bands 3 to 8 are balanced to ground, to minimize capacitive pick-up by the loop at the higher frequencies. The secondaries of transformers (81-87) of bands 1 to 7 are switched by section G of the band switch (132). The rear of section G shorts the transformer secondary of the band below the one in use. The antenna transformer (88) of band 8 couples the loop directly to the modulator (115). The secondary is switched by section J. The front section (5a) of the gang condenser tunes the antenna circuit of bands 1 to 7. The middle section (5b) of the gang tunes band 8 antenna circuit.
- (2) The rod or sensing antenna (120) is coupled to the secondary antenna circuits through one or more of the resistors surrounding switch section E. The "sensing" antenna is used only in bands 1 to 6. Switch section E selects the resistance suitable for each of these bands. The function of the resistance introduced between the sensing antenna and the tuned circuit is to attenuate the sensing voltage without shifting its phase; it also helps "match" the unequal impedances of sensing antenna and secondary circuits. The push switch (130-1) in series with the sensing circuit, grounds the sensing antenna when it is not used. When the switch (130-1) is pushed the ground is disconnected and the sensing circuit is completed. The low

capacitance plug (126-1) and socket (127-1) serve to connect antenna (120) to the switch (130-1). Plug (126-2) and socket (127-2) carry the circuit within the chassis. The ground to within the chassis is made through pin 5 on the plug (124) and contact 5 on the connector (125).

- (3) The output of the r-f tube (118-1) is coupled to the modulator (115) through the r-f transformers (89-95) for bands 1 to 7 only, since band 8 uses no r-f amplification. The primaries of these transformers are switched by section I of the band switch (132). These primaries are resonant at a frequency below the respective bands used. In the case of bands 1 and 2 external capacitance is added to effect this resonance. The other primaries are resonated with distributed capacitance. The secondaries are switched by the front of section J of the band switch (132). The rear of section J shorts the transformers secondary of the band below the one in use. All of the r-f transformers are wound to have capacitance coupling aid the inductive coupling. Capacitor (20) serves to increase the distributed-capacitance coupling, particularly at the higher frequencies. The r-f secondary circuits are capacitance coupled to the signal grid of the modulator (115).
- (4) The oscillator transformers (96a, b; 97a, b; 98a, b; 99) are used with the separate oscillator tube (116) in a plate-tuned circuit. Feedback in bands 1, 2 and 3 is obtained by returning to the oscillator grid the voltage developed across the series padding capacitors. For example, in band 1, the feedback voltage is obtained from the adjustable series padder (3-1) shunted by the fixed series capacitor (12). At the higher frequencies, bands 4 to 8, this feedback is supplemented by inductive feedback provided by the primaries of transformers 97b, 98a, 98b and 99. Section K of the band switch (132) switches the feedback circuits. The secondaries are switched by the rear of section L. The front of section L shorts the secondaries of the two bands below that in use. The end section (5c) of the gang capacitor tunes the oscillator transformers. In bands 1 and 2, fixed capacitors (11-1) and (11-2) are in shunt with the trimmer (3-2) and (3-4) in order to obtain the required tuning range. In bands 3 to 6 the trimmers: (2-5), (1-12), (1-13) and (1-14) are used to adjust the upper tuning limit of each band. Oscillator transformer (99) is used for both bands 7 and 8. In band 7, the oscilla-

tion frequency is above the signal frequency. In band 8 the second harmonic of the same oscillation frequency is used; but this harmonic is below the signal frequency. The trimmer (1-15) is used to adjust the upper tuning limit of band 7. With this adjusted, the upper tuning limit of band 8 is simultaneously set because of the designed frequency relation. The lower tuning limit of bands 7 and 8 is not adjustable since the series capacitor (18) is fixed. In all bands, the oscillator voltage is coupled from the "tank" circuit to the modulator injection grid, through the capacitor (21-1).

- (5) The plate of the modulator (115) connects to switch section D which selects either of two i-f channels depending on the band used. Bands 1, 3, 4 and 5 use the 455-kc i-f channel. Bands 2, 6, 7 and 8 use the 910-kc i-f channel. The higher frequency bands 6, 7 and 8 require the higher i-f in order to provide better image rejection and to keep the tuning control from being excessively critical or "razor sharp". Band 2 includes 455-kc in its tuning range and therefore it must also use the 910-kc channel Transformers: (101) and (103) are in the 455-kc channel. Transformers: (102), (105) and (104) are in the 910-kc channel. Both the primaries and secondaries of the four double-tuned transformers are switched by sections D, B and C, A of the band switch (132). The single-tuned interstage transformer, (105), is not switched. It is tuned to 910 kc by distributed capacitance and the trimmer (1-16). At 455 kc the interstage transformer provides no additional selectivity and only a nominal amplification in conjunction with the first i-f amplifier tube (118-2). The output from either channel is rectified in the diode circuit of the detector (117). A "tweet filter" (53-2) and (23-2), in the diode load circuit removes most of the i-f from the desired audio voltage.
- (6) The audio signal is coupled to the grid of the first a-f amplifier grid through the capacitor (27). The output from the audio section of tube (117) is coupled to the output tube (118-4) through the capacitor (28). The output tube, triode connected, is coupled to Headset HS-34-A through the audio transformer (107). The secondary of this transformer is connected to panel Jack JK-34-A and to the HEADSET terminals on the control plate. Connections to the latter are carried through the 4-wire cable and plug arrangement (123), (122).

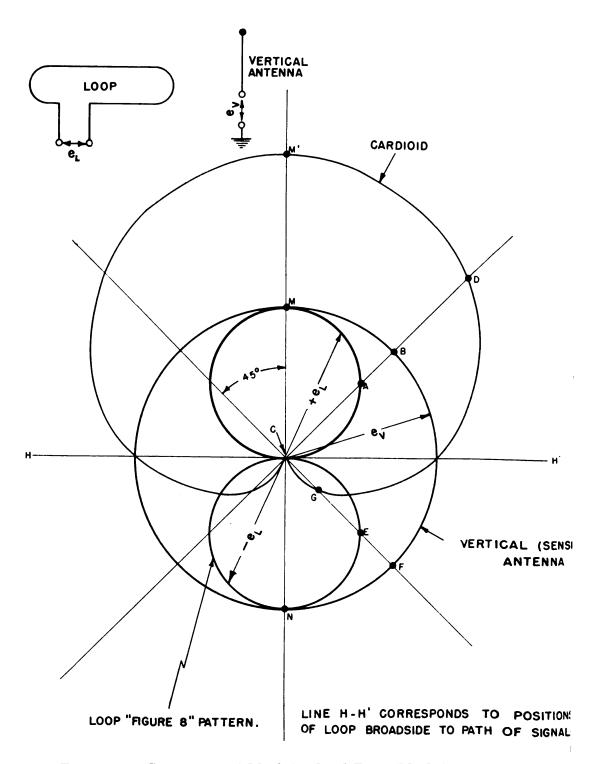

Figure 18. Derivation of Ideal Cardioid From Ideal Antenna Patterns

- (7) The beat-frequency oscillator which is used for monitoring unmodulated signals is tuneable to 454 kc by means of trimmer (3-9). The oscillator uses a tube (118-5) in a plate-tuned, inductive feedback circuit. The secondary of the b-f oscillator transformer (106) is shunted with a fixed capacitor (21-3) to provide the proper frequency range. Normally the b-f oscillator is tuned to 454 kc, giving a 1000-cycle beat with the 455 kc i.f. The second harmonic produced by the b-f oscillator is used to beat with the 910 kc i.f. The BFO OFF-ON switch (131-1) in the "B" supply circuit, permits the oscillator to be controlled from the top plate. Coupling from the b-f oscillator to the i-f channels exists through the common supply circuits and by virtue of the strong fields the oscillator produces.
- (8) Since this receiver is required to give an auditory indication of changes in signal input, the use of A.V.C., as in conventional receivers, is out. Accordingly a manual volume control system is used. This system not only reduces the audio output, but increases the bias on certain tubes (118-1) and (118-2) so that these are not overloaded by strong signals. Electrically, the panel volume control (69) works the same as the control-plate control (70). The VOLUME CONTROL TRANSFER switch (130-2) connects one or the other in series with the "B" lead. The voltage drop in the control combined with the "A" battery voltage is applied to resistors (59) and (60). The junction of the latter provides a bias voltage suitable for the grid of the r-f tube (118-1). A similar arrangement provides bias for the first i-f tube (118-2), with the exception that only half the volume control voltage-drop is used. Resistors (56-3) (56-4) divide the voltage drop. The other divider (68-1) and (68-2) in the grid return of the first i-f tube (118-2) again reduces the voltage in suitable proportion relative to the potential of the filament.

## 19. Directional Characteristics of Antennas.—

a. The directional characteristic of a loop antenna is shown in figure 18. This pattern is popularly known as a "figure 8". Under ideal conditions this pattern could be obtained by measuring the roltage at the terminals of a loop at successive angular positions of the loop as is it rotated through 360 degrees in a horizontal plane. The voltages measured are plotted as radial distances from the

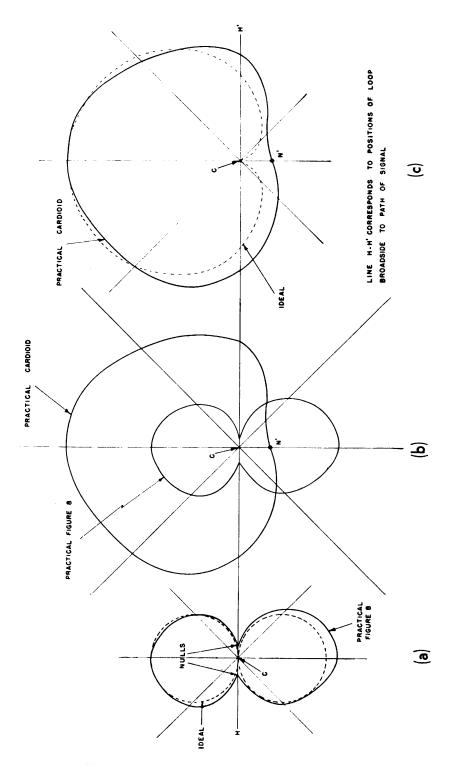

Figure 19. Practical Cardioid and Figure 8 Antenna Patterns

center of the graph at C, figure 18. An examination of the ideal "figure 8" pattern shows that for two positions of the loop the voltage is zero. In these two positions the loop is broadside to the arriving waves. The maximum voltage points on the "figure 8" at M and N correspond to the two positions where the loop is in line with the path of the waves, that is at  $\pm 90^{\circ}$  from the broadside positions. The two positions giving zero voltage are referred to as the "nulls". The nulls are of great importance since they are a sensitive means of determining the path of the signal. However, when ideal conditions are no longer obtained (in a practical case), the nulls of the "figure 8" don't go to zero, as shown for the "practical" case in figure 19(a). Nevertheless, they can still be used as before, except that instead of observing an absolute zero, the minimum must be found.

- b. Since the voltage produced by a small loop in picking up a radio wave of usual strength is much too low to measure by any direct means (such as a meter), it must be amplified. That is the function of all the tubes from the antenna circuit to the headset. When the amplification of these tubes is adjusted so that no tube is overloaded, the sound heard in the headset is proportional to the voltage at the loop terminals. The ear can then hear the "figure 8" pattern as the receiver and loop are rotated, and judge the "null" positions.
- c. In direction-finding it is necessary to know more than just the path of the signal, namely whether the signal is "coming or going". The latter operation is commonly referred to as finding the 'sense" of the direction, or more simply just as "sensing". That is, n addition to the loop, which indicates by means of the "nulls" either of two directions from which the signal may be coming, a sensing levice is needed to pick up the true direction. This need is filled by he vertical rod antenna (called "sensing" antenna) used in conjunction with the loop. The directional characteristic of a vertical antenna under ideal conditions is shown in figure 18 by the large circle. Stated in words, figure 18 says that the voltage produced by a vertical intenna remains the same when rotated about its axis. This is popularly known as a "non-directional pickup".

If the voltage produced by a loop and the voltage produced by vertical antenna (under ideal conditions) are added together algebraically), a new directional characteristic is obtained. This pat-

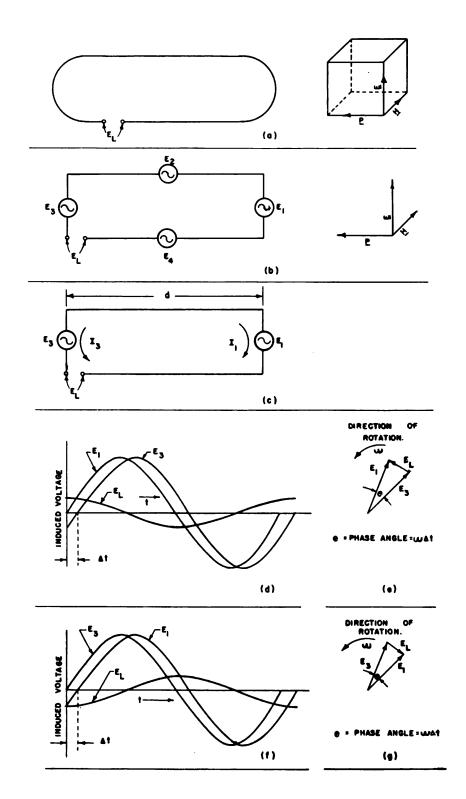

Figure 20. Equivalent Loop Circuit and Voltage Diagrams

tern, likewise shown in figure 18, is called a cardioid because of its heart-like shape. The reason this shape is obtained when the "figure 8" and the circular pattern are added together is that the voltage in the lower lobe of the "figure 8" is opposite in time-phase to the voltage in the circle pattern, while the time-phase of the voltage in the upper lobe of the "figure 8" is in agreement with that of the circle pattern. Thus for each direction above the horizontal line H-H' (running through the nulls) the voltages add together such as: CA + CB = CD; and for each direction below the horizontal line the "figure 8" voltage subtracts from the circle voltage, such as: CF - CE = CG.

Compare the cardioid with the "figure 8". It is evident that the two positions of the loop which gave outputs of equal magnitude, CM and CN, now are distinguishable in the cardioid in which the voltage CM' is twice CM and in which CN is reduced to zero. Thus the cardioid provides the needed sensing since you are now able to tell that the signal is coming from the direction in which the CM' observation is made. You should understand at this point that the cardioid is not a "sharp" indicator of direction because the change in voltage to either side of CM' is very gradual, but there is no need for the cardioid giving a sharp indication of bearing. This is obtained from the "figure 8" loop voltage, where the change to either side of the nulls is much more rapid. So the two patterns must be used together, each for its specific purpose. In a practical case, this is even more necessary since the ideal cardioid is no longer obtained.

The most notable departure of an actual sense curve or practical cardioid is shown in figure 19 (c) by the failure of the curve at N' to go through C. This is caused by the failure of the voltages from loop and vertical antenna to cancel each other as a result of phase shift and unequal "pickup".

## d. Theoretical Analysis of Loop Directional Characteristics.—

An electromagnetic wave, travelling with the velocity of light, c, intercepts a stationary loop and induces voltages in it. For the purposes of this analysis the loop shape of figure 20(a) can be replaced by an electrically equivalent loop which is rectangular and has its terminals at one corner as in figure 20(b). The induction in the

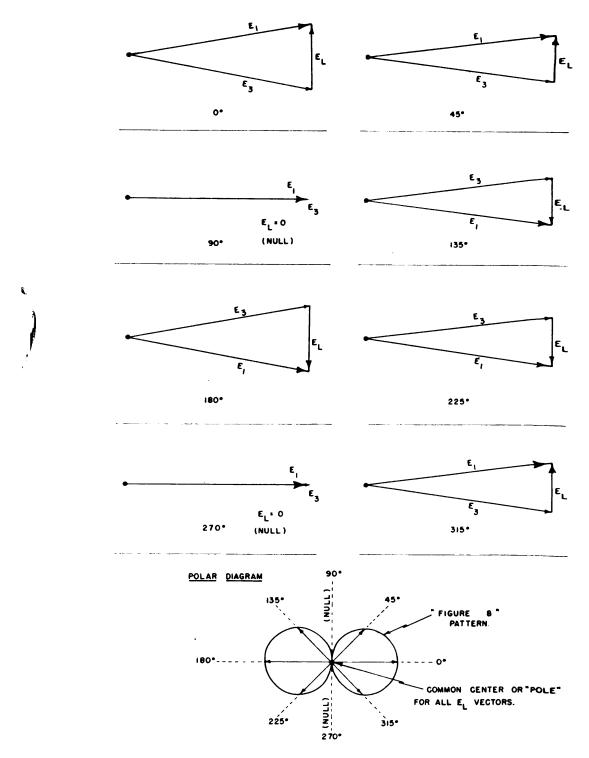

Figure 21. Synthesis of the "Figure 8" Pattern by Vector Diagrams

loop as a whole can be considered as occurring in the four sides of the loop separately. Consequently, for all practical purposes the rectangular loop can be replaced by an equivalent circuit having four generators:  $E_1$ ,  $E_2$ ,  $E_3$  and  $E_4$ , as in figure 20(b). Assuming that the electromagnetic wave is a vertically-polarized, plane wave, the electric vector E, the magnetic vector E and the propagation vector E at any given instant of time would be directed as in figure 20(a). That is, the electric vector E is vertical, while the magnetic vector E is horizontal and both are perpendicular to the propagation vector E. These vectors are shown in relation to a cube to help you visualize the spatial relation of the vector quantities which must of necessity be illustrated on a flat page.

If the loop is oriented in the direction of receiving maximum signal, E will be in the plane of the loop and parallel to the two vertical sides of the loop and will induce voltages  $E_1$  and  $E_3$  in these two sides. Since E is perpendicular to the horizontal sides of the loop, no voltage is induced in them, so that  $E_2$  and  $E_4$  are zero in this instance, and need not be considered further. It might be pointed out in passing, however, that if the loop is tilted with respect to the wave, as for example would be the case if the receiver is not held parallel to the ground, or if the wave were a downcoming wave reflected from the ionosphere, E would not be perpendicular to the two horizontal arms of the loop and voltages would be induced in them. But this more complicated case will seldom be found in the use of Radio Set SCR-504-A, and so will not be considered further here.

It is seen that the voltages  $E_1$  and  $E_3$  of figure 20(c) oppose each other and at first glance you would suppose that they are equal and would cancel each other. The two voltages  $E_1$  and  $E_3$  are equal in magnitude but they are not equal in time-phase. This is due to the time  $\triangle$  t, required by the wave to travel the additional distance, d, between the two sides of the loop. This can be stated mathematically by:

$$\triangle \mathbf{t} = \frac{\mathbf{d}}{\mathbf{c}}$$

where d is the distance between the two sides of the loop and c is the velocity of the electromagnetic wave. This means that the alternating voltage E<sub>1</sub> will lead the alternating voltage E<sub>3</sub>. Mathematically,

we can write:

$$E_1 = E_0 \cos \omega t$$

$$E_3 = E_0 \cos \omega (t - \triangle t)$$

$$E_{L} = E_{1} - E_{3} = E_{0} \left[ \cos \omega t - \cos \omega (t - \triangle t) \right]$$

 $E_L = E_0 [\cos \omega t - \cos \omega t \cos \omega \triangle t - \sin \omega t \sin \omega \triangle t]$ If  $\triangle$  t is very small; that is, if the distance d is very much less than half a wave length of the electromagnetic wave signal, then

$$E_{\rm L} = - E_0 \omega \triangle t \sin \omega t$$

This can be illustrated graphically and vectorially, as in figures 20(d) and 20(e) respectively.

Obviously, if the signal comes from the left, instead of from the right, as in figure 20(a), the voltage induced in the  $E_3$  side of the loop will lead the voltage induced in the  $E_1$  side by the phase angle  $\omega$   $\triangle$  t. This gives rise to the situation shown in figures 20(f) and 20(g). In figure 21 are shown the vector diagrams corresponding to successive positions of the loop relative to the signal path using  $45^{\circ}$  intervals from  $0^{\circ}$  to  $360^{\circ}$ . The resultant loop voltages,  $E_L$ , for these positions when plotted in the form of a polar diagram give the "figure 8" pattern.

## 20. Battery Charger PE-128-A. (Refer to figures 9, 34)

- a. Battery Charger PE-128-A is designed to operate from either a 6-volt or a 12-volt vehicular battery. To partially guard against application of the wrong supply voltage to the charger circuits, a separate conductor for the 12-volt connection is included in Cord CD-658-A. Thus, if the SUPPLY switch (133) is accidently thrown in the wrong direction, no fuses are blown as long as the battery cord is properly connected.
- b. The energizing coil of the synchronous vibrator (119) is designed to operate on 6 volts; accordingly, the current through it is held to the design value by resistor (75-1) which is connected in series for 12 volt operation.
- c. The main function of SUPPLY switch (133) is to connect the transformer (111) primaries in parallel for 6-volt operation, or in series for 12-volt operation. This transformer has two secondaries. The center-tapped secondary is operated in conjunction with the contacts S.S. of the vibrator to supply d.c. for the "B" circuit. The other secondary supplies square wave a.c. to the full-wave selenium rectifier (140) of the "A" circuit.

d. The "B" current is filtered by the tuned choke (112) and the shunt capacitors of (36a, 36b). The dual potentiometer (76) provides adjustment of the charging rate. The two "B" batteries (Batteries BB-52) are connected in series for charging by means of the terminal plate (141). The 3-position METER RANGE switch (135) connects the 100-volt range of the voltmeter (143) to either of the two "B" batteries for measurement of the battery terminal voltages while charging or discharging through a fixed load (79). The METER RANGE switch when in either of the two "B" positions causes the milliammeter (142) to read the current through both "B" batteries. The discharge current applied to the resistor (79) load by the BATTERY LOAD TEST does not pass through the milliammeter.

The d-c output of the selenium rectifier (140) is filtered by resistors, (75-2) and (77), and the shunt capacitors of (37a, 37b). The rectifier output is series-connected with the supply battery, when 6-volt operation is used, thus giving an output voltage which is the sum of the supply voltage and the filtered rectifier outout. When 12-volt operation is used, the a-c input to the rectifier (140) is disconnected and the supply battery furnishes charging surrent through the rectifier. For either mode of operation, the chargng rate is adjusted with the tapered potentiometer (77). When in he "A" position the METER RANGE switch (135) connects the 20-volt range of the voltmeter to the "A" battery for measurement of the battery terminal voltage while charging or discharging through fixed load (78). The milliammeter reads the "A" charging curent when the meter switch is at "A". The discharge current applied o the resistor (78) by the BATTERY LOAD TEST does not pass hrough the milliammeter.

Fuses are connected in various circuits to minimize possible amage by failure of circuit components or by abuse of the charger. he 4-ampere primary fuse (137) protects the windings of the transormer from excessive current caused by sticking of the vibrator or pplication of 12 volts to the 6-volt circuit. The primary fuse will lso blow if capacitor (36a) breaks down. The 1/2-ampere fuse 138) protects the rectifier circuit and resistors. The 1/16 ampere 1se, (139), protects the choke (112) and the resistor (76) against amage by failure of capacitor, (36b), or misuse of the equipment.

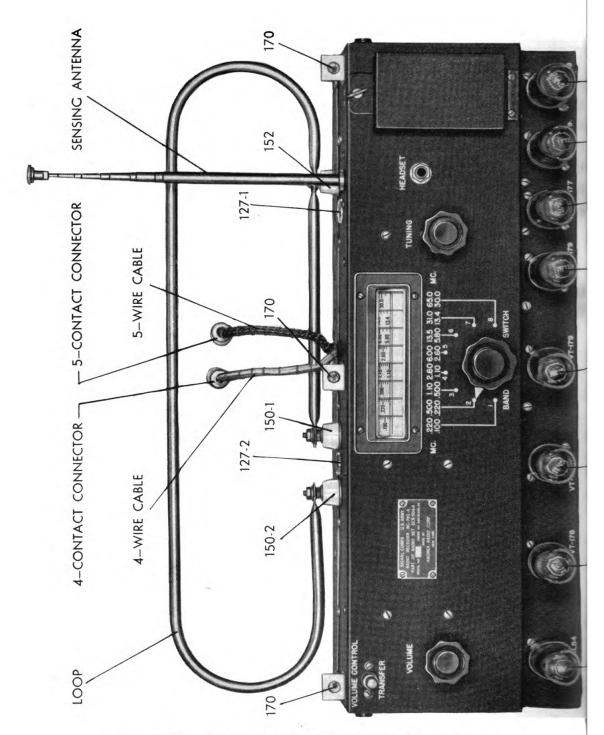

Figure 22. Radio Receiver BC-792-A, Chassis Removed From Suitcase, Front View

# SECTION IV MAINTENANCE

#### 21. General Instructions.—

Operating personnel shall confine their maintenance and repair servicing of this equipment solely to the extent indicated in the following paragraphs. If trouble develops which does not respond to the treatment outlined in the "Trouble Charts", the equipment will require the services of Signal Corps maintenance personnel thoroughly experienced in its repair. Any attempts by inexperienced personnel to service the equipment indiscriminately may result in great damage.

## 22. Trouble Chart for Radio Receiver BC-792-A.—

22.	22. Trouble Chart for Radio Receiver BC-792-A.—			
Trouble	e Probable Causes	Remedy		
Receiver	POWER switch OFF.	Throw POWER switch to ON.		
Dead.	VOLUME control turned down.	Turn VOLUME control to right.		
	"A" battery (BB-51) dead.	Replace "A" Battery (BB-51).		
	One or both "B" batteries (BB-52) dead.	Replace "B" Batteries (BB-52).		
	One or more batteries not making contact because of incomplete insertion.	Make sure the batteries are completely pushed in.		
	One or more battery prongs corroded.	Remove batteries and clean prongs if necessary.		
	Headset HS-34-A not plugged in.	Insert tips of Cord CD-655-A into HEADSET jacks on control plate.		
	Receiver R-27-A disconnected from Cord CD-655-A.	Insert tips of Cord CD-655-A into jacks of receiver R-27-A.		
	Cord CD-655-A defective.	Replace with spare cord.		
	One or more tubes loose in socket.	Push the tubes into sockets firmly.		
	One or more tubes defective.	Replace all the tubes with the cor- responding types from one of the spare tube kits. Don't throw away the old tubes. Mark them and wait		

for a chance to test them and find the defective tube. Throw away only the defective tube or tubes.

Trouble	Probable Causes	Remedy
Receiver Dead. (Con't)	4-Contact connector (123) removed from plug (122)	Open leather curtain over panel by turning three small catches to left. Push connector (123) at end of cable into 4-prong plug (122) at tached to vertical plate. (See figures 10, 22.)
	5-Contact connector (125) removed from plug (124).	Open leather curtain over panel by turning three small catches to left. Push connector (125) at end of cable into 5-prong plug (124) attached to vertical plate. (See figures 10, 22.)
Received Signals Weak.	"A" battery (BB-51) weak.	Replace "A" battery (BB-51).
W sum	One or both "B" batteries (BB-52) weak.	Replace "B" batteries (BB-52).
	One or more batteries making poor contact because of incomplete insertion.	Make sure the batteries are completely pushed in.
	One or more battery prongs corroded.	Remove batteries and clean prongs if necessary.
	One or more tubes loose in socket.	Push the tubes into sockets firmly.
	One or more tubes defective.	Replace all the tubes with the corresponding types from one of the spare tube kits.
	Excessive moisture in suitcase as a result of long exposure to rain.	Allow receiver to dry out in a well-ventilated place. This may take a day or so depending on the existing humidity of the atmosphere. Opening the leather curtain will speed up the process.
	A poor location for reception of radio signals, such as inside a metal structure or a natural "dead spot".	Go to some other location.

Trouble	Probable Causes	Remedy
No SENSE ndication.	Rod antenna has not been extended to its full length.	Extend rod antenna completely so that you see all 5 sections above top of suitcase.
	Single-prong plug (126-1) removed from socket (127-1).	Open leather curtain by turning 3 catches. Insert plug (126-1) in socket (127-1) near base of "sensing" antenna.
	Single-prong plug (126-2) removed from socket (127-2).	Open leather curtain over panel by turning three small catches to left. Insert plug (126-2) in socket (127-2) between terminals of loop.
	SENSE button not pushed down far enough.	Push SENSE button all the way down when making sensing observations.
	Peculiar nature of signal or location you're in (in- side a building or near a large structure).	Try another signal or another location. Refer to paragraph 15.
	Your body may be too close to sensing antenna.	Hold "sensing end" of suitcase away from your body.

If you have trouble which is confined to one or two bands only, and a change of location doesn't help, then the receiver should be inspected by experienced personnel.

## 23. Trouble Chart for Battery Charger PE-128-A.—

Trouble	Probable Causes	Remedy
harger 'dead'',	Supply battery dead.	Replace supply battery with a fresh one.
hat is: weither "A" nor "B" surrent.	Cord CD-658-A wrongly connected.	Check conductor markings against voltage and polarity of vehicular supply battery.
	Clips on battery cord not making contact with sup- ply battery terminals.	Check against dirt and corrosion on clips and terminals. Make sure clips "bite" into terminals of sup- ply battery.
	SUPPLY switch in wrong position.	Make sure switch is at 6V. SUPPLY or 12V. SUPPLY, according to voltage of supply battery.

Figure 23. Battery Charger PE-128-A, Rear View

Trouble	Probable Causes	Remedy
harger dead", uat is: wither "A" r "B" rrent. Con't)	Primary fuse blown.	*Remove 4A. (137) fuse from "active" fuse holder (the one nearer front of charger). Examine fuse by eye to see if it has opened up or blown. *Put spare 4A fuse in "active" holder if necessary.
	Both "A" and "B" fuses blown.	*Remove these fuses (138, 139) and replace with spares if necessary.
	Vibrator loose or removed from socket.	Check insertion of vibrator in its socket.
	Vibrator defective.	Replace with spare vibrator if available.
	"A" and "B" batteries not plugged in sufficiently.	Make sure these batteries are pushed "home", in their proper sockets.
o "A" urrent, ut "B" urrent .K.	"A" and "B" batteries not filled sufficiently to pass a charging current.	Add acid as required. See paragraph 8.
	"A" battery (BB-51) not plugged in completely.	Push "A" battery all the way in.
	"A" battery prongs dirty or corroded.	Remove dirt and corrosion from "A" battery prongs.
	"A" battery not filled sufficiently.	Add acid as required. See paragraph 8.
	"A" fuse blown.	*Remove ½A. (138) fuse from "active" fuse holder. Inspect it by eye to see if it has opened up or blown. Put spare ½A. fuse in "active" holder if necessary.

No "B" current, but "A" current O.K.	One or both "B" batteries not plugged in completely.	Push both "B" batteries all the way in.
	"B" battery prongs dirty or corroded.	Remove dirt and corrosion from "B" battery prongs.
	One or both "B" batteries not filled sufficiently.	Add acid as required. Remember just one unfilled cell is enough to stop passage of charging current. See paragraph 8.
	"B" Fuse blown.	*Remove 1/16A. (139) fuse from active fuse holder. Inspect it by eye to see if it has opened up or blown. Put spare 1/16A. fuse in "active" holder if necessary.
	Vibrator defective.	Replace with spare vibrator.
Low "A" and "B" current.	Vehicular supply battery weak.	Replace supply battery by one that is charged and up to its normal voltage.
	Both "A" and "B" batteries may be fully charged and thus no longer pass much current because of their high terminal voltages.	Check voltage of batteries, using BATTERY LOAD TEST, see paragraph 9. If their voltages under load are high, then continue charging at no more than "trickle rate".
	Both "A" and "B" batteries may not be sufficiently filled.	Add acid as required. See paragraph 8.
	Vibrator defective.	Replace with spare vibrator if

#### \*CAUTION:

Whenever Battery Charger PE-128-A is made inoperative by a fuse blowing, find the cause and correct it before inserting a spare fuse. If the fuse was blown by improper connection of the battery cord, excessive charging rate or any other abuse of the charger, how to remove the cause will be evident. However, if all the rules in the trouble chart are followed and fuses continue to blow, then it's very likely that some circuit component has failed. In this case, the repair of the equipment shall be undertaken only by experienced personnel.

available.

- a. Because of the inherent stability of the tuned circuits used n Radio Receiver BC-792-A, it is unlikely that the receiver will have o be realigned in the field. However, if the sensitivity of any band hould fall off considerably under normal operating conditions, it may become necessary to make alignment adjustments. Realignment s also necessary if any coils are replaced. If the dial calibration hould depart seriously, it may also be necessary to make adjustments on the high frequency oscillator circuits. Before any attempts re made at realignment, it should be definitely ascertained that here are no other factors causing the difficulty experienced. Study he circuit diagram carefully before attempting to make any adustments, since careless readjustment of the circuit trimmers can take the receiver completely inoperative.
- b. Equipment Required for Alignment of Radio Receiver C-729-A.—
- (1) Signal Generator. Range 100 kc to 65 mc. The generator hould be well shielded and provided with an attenuator for reducing resignal to at least 10 microvolts.
- (2) Output load box—with 250-ohm position and capable of leasuring 1 milliwatt of power.
- (3) Radiating loop. Construction of this loop is described in aragraph 25.
  - (4) Insulated screw driver.
- (5) Coupling capacitor. A paper capacitor with a capacitance .05 uf equipped with insulated alligator clips is satisfactory.
- c. First you must remove the receiver from the suitcase. Take e following steps:—
- (1) Remove the four flat-head screws from the suitcase. You'll id the heads of two of these on the bottom side of the suitcase and is on each side in the position where they are normally concealed the suitcase lid. (See figure 2.)
- (2) Unfasten the leather flap by means of the three wing catches er the front panel of the receiver.

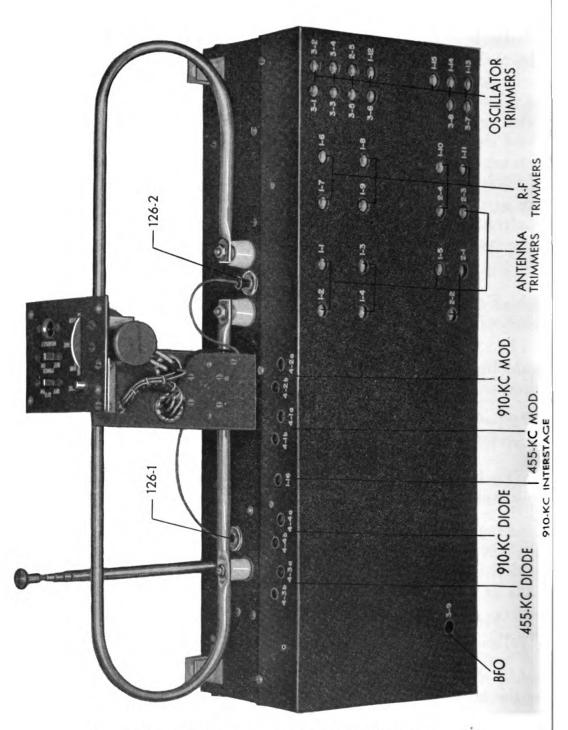

Figure 24. Radio Receiver BC-792-A, Chassis Removed From Suitcase, Rear View

- (3) Disconnect the four-prong (123) and five-prong (125) connectors from the control plate.
- (4) Remove the single-prong plugs (126-1, 126-2) from their respective jacks on the top of the receiver.
- (5) Unscrew the brass button at the top of the sensing antenna (120). Make sure that the sensing antenna is completely collapsed so that it will not catch when removing the receiver.
- (6) Grasp the receiver with two hands and pull it out of the suitcase, tilting the bottom slightly so that the loop clears the switches on the control head.
- (7) Remove the four screws holding the control head to the top of the suitcase.
- (8) Remove the two wood screws holding the control head to the block inside the suitcase. Remove the control head and reconnect it to the receiver by using the plugs and connectors.
- d. Since it's generally simpler to realign the receiver by connecting to points within the chassis, remove the ten screws securing the metal cover to the main chassis (there are three each of these screws on the top and bottom of the receiver, and two at each end). The cover may then be pulled straight off the chassis. I-f alignment may be made with the cover removed but alignment of the other circuits should be made only with the cover in place.

## e. I-F Alignment.—

Connect the signal generator to the signal grid of the modulator tube (pin 6 of 115), through the .05 µf coupling capacitor. Connect the ground side of the signal generator to any convenient point of the chassis. Be careful in connecting the clip lead to the tube socket so that it does not short circuit or touch any other circuits. It is best to make this connection before inserting the batteries. Thoroughly check the connection and position of the alligator clip, then insert batteries BB-51 and BB-52 as usual. Connect the putput load box to the headset terminals of the receiver. This can be done conveniently by using Cord CD-655-A plugged into the HEADSET terminals on the control plate. Remove Receiver R-27-A from the other end of the cord and then connect the cord to the output lox. An alternative means for connecting the output box is to nsert a cord, terminated in Plug PL-55 in the HEADSET jack on

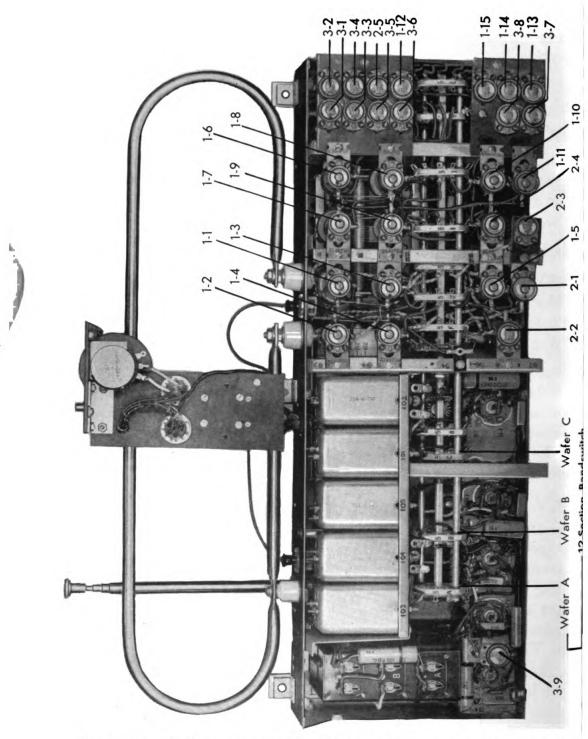

Figure 25. Radio Receiver BC-792-A, Chassis Removed From Suitcase, Rear View With Cover Removed From Chassis

he receiver panel. Make certain that the output load box is adjusted 10 250 ohms and that the meter scale is such that 5 milliwatts will not overload the instrument. Throw the power switch to ON and tune the receiver to the low end of band 2. Advance the VOLUME control to maximum. Set the signal generator to 910 kc with 30% (400-cycle or 1,000-cycle) modulation and increase the output until the signal produces a deflection of approximately 1 milliwatt on the output meter. There are five adjustments to be made for the 910 kc i-f channel. Use the insulated screw driver to rotate the trimmers (4-2a, 4-2b, 1-16, 4-4a, 4-4b) in the i-f transformers 102, 104, 105. Each trimmer should be adjusted to produce maximum signal output. Reduce the output of the generator so that the reeiver remains in the region of 1 milliwatt, otherwise the receiver will be overloaded as it is brought into alignment. When you have adjusted these trimmers once, it's a good idea to go through the same procedure again to be sure that each is set at its best position. Finally, check the peak response frequency of the i-f channel by tuning the signal generator and observing the frequency giving the maximum output. The frequency observed should be within 2 or 3 kc from 910 kc.

The 455-kc channel is aligned by a similar procedure except that there are only four adjustments to be made. Set the signal generator to 455 kc with 30 per cent modulation. Tune the receiver to he low end of band 1. Advance the VOLUME control to maximum is before. Increase the signal generator output until the signal proluces a deflection on the output meter. Adjust the trimmers (4-la, I-lb, 4-3a and 4-3b) in the i-f transformers 101 and 103 for maxinum output. After the initial adjustment, repeat the procedure to issure optimum adjustment of each. Finally, check the peak response requency by tuning the signal generator for maximum output. The requency observed on the generator should be within 1 or 2 kc of 155 kc; the sensitivity at the modulator grid at 910 and 455 kc for milliwatt output should be approximately 15 microvolts and 30 nicrovolts respectively. These figures are based on normal battery oltage and tubes that are in good condition. Any considerable departure in modulator grid sensitivity is an indication of trouble. lefore any of the other circuits are aligned, put the cover back in lace.

## Table of I-F Alignment

Band	Sig. Gen. Frequency, KC	Adjust Trimmers (Fig. 24)
2	910	4-2a
2	910	4-2b
2	910	1-16
2	910	4-4a
2	910	4-4b
1	455	4-1a
1	455	4-1b
1	455	4-3a
1	455	4-3b

## f. Alignment of Oscillator R.F. and Antenna Circuits.—

Since it is not convenient to make a direct electrical connection to the receiver circuits from the signal generator when the cover is in place, it is necessary to use a radiating loop connected to the generator. The construction of a loop of this type is described in paragraph 25. Connect the loop to the signal generator and place it approximately as shown in figure 26 with respect to the receiver. It should be realized in advance that if the circuits of the receiver are seriously out of alignment, the signal generator output may have to be increased considerably in order to produce a deflection on the output meter. If the dial calibration departs from the correct frequencies produced by a reliable signal generator or frequency standard. then it will be necessary to adjust the oscillator trimmers. There are two oscillator trimmers for each band up to and including band 6. For example, in band 1, trimmer 3-2 affects the dial calibration principally at the high frequency end of the band. (See par. 24f(1).) Trimmer 3-1 affects the dial calibration principally at the low frequency end of the band. However, there's a certain amount of interdependence between these two adjustments so it will be necessary to readjust each more than once until satisfactory results are obtained. In the higher frequency bands be careful not to confuse the signal with the image when adjusting oscillator trimmers. Remember that in bands 1 to 7 the oscillator is always above the signal frequency, that is, of the two possible responses that can be obtained when tuning the signal generator, the lower frequency is the one to use. The adjustment of band 7 oscillator circuit is made solely by trimmer 1-15 at the high frequency end of the band. Since band 8 uses the same oscillator circuit as described in paragraph 18a (4), no further adjustment is required. The low frequency end of band 7 and 8 oscillator circuit is not adjustable.

After the oscillator circuits have all been adjusted so that the dial calibration reads correctly, adjust the r-f circuits at the high frequency end of the bands so that maximum response is obtained from the output meter. This is done by adjusting the r-f trimmers at the frequencies given in paragraph 24f(1). For example, in band 1, trimmer 1-6 is adjusted at 205 kc until maximum output is obtained. Since there is no r-f stage for band 8, only 7 r-f trimmers have to be adjusted. The antenna circuits for bands 1 to 8 inclusive are also adjusted at the high frequency end of the bands. For example, trimmer 1-1 is used to adjust for maximum output at 205 kc in band 1. In general it is preferable to adjust both antenna and r-f circuits for one band before proceeding to the next. Repeat each adjustment several times to be sure you've obtained the best results. At the higher frequencies be sure that the oscillator frequency is accurately tuned with respect to the signal when the alignment adjustments are being made. As a final check on the over-all electrical sensitivity of the receiver, note the necessary signal generator output in microvolts necessary to produce 1 milliwatt on the output meter when the loop to loop distance is 20 inches. The signal generator output divided ov 10 gives the field strength in microvolts per meter at a distance of 20 inches, when the loop described in paragraph 25 is used. The sensitivity of the receiver under normal conditions averages about 10 microvolts per meter in bands 1 to 4 inclusive. The sensitivity n microvolts per meter in bands 5 to 6 will average from 50 to 100 nicrovolts per meter under normal conditions. At the higher frejuencies encountered in bands 7 to 8, the introduction of various purious effects makes the determination of the receiver sensitivity by this method very unreliable in the absence of elaborate test equipment. The only dependable means for ascertaining that the receiver is functioning properly is to listen to the noise level or by ctual use of the receiver to pick up signals of known field strength.

## (1) Table of Oscillator, R-F and Ant. Alignment

8	29.0 60.0		- -	2-3

<sup>\*</sup>Adjust these only if dial calibration is off by more than one division.

## g. Adjustment of B-F Oscillator.—

- (1) The necessity for readjusting the b-f oscillator is evident when an audible beat is no longer produced when the b-f oscillator switch is thrown to ON, after the receiver is tuned to a signal. The best procedure for adjusting the b-f oscillator is to radiate from the loop a signal of 455 kc modulated with 400 cycles.
  - (2) Tune the receiver near the low end of band 3.
- (3) Increase the signal generator output until the signal is clearly audible in the headset. Make sure that the signal generator is tuned exactly to the peak response frequency of the 455 kc channel. Switch off the 400 cycle modulation.
  - (4) Throw BFO switch to ON.
- (5) Adjust trimmer 3-9 so that the audible beat is approximately 1000 cycles. Since there are two positions of 3-9 which will give the 1000-cycle beat, you'll have to find out by trial and error which of

these positions represents the frequency of the b-f oscillator below 455-kc. You can do this best by observing in which direction the signal generator must be tuned in order to produce zero beat.

- (6) Since the 910-kc i-f channel utilizes the second harmonic of the b-f oscillator, no further adjustment of 3-9 need be made for the bands using the 910-kc channel. However, if you want to check the performance of the b-f oscillator in conjunction with the 910-kc i-f, proceed as follows:
  - (a) Tune the receiver to the high end of band 2.
- (b) Tune the signal generator to produce peak output when radiating at or near 910 kc with the modulation turned on. Then remove the modulation and throw BFO switch to ON. The beat produced should be within the audible range. If the ratio of the i-f channel peak frequencies is exactly 2-to-1, the beat frequencies also will be in the ratio 2-to-1.
- (7) If you don't get an immediate response from the b-f oscillator it is not too serious because in normal use, if you don't hear the beat immediately when you turn on the b-f oscillator, you can make the beat audible by a slight retuning of the receiver.

### (8) Table of B-F Oscillator Adjustment

Sig. Gen. Frequency Kc.	Dial Frequency Kc.	Adjust Trimmer
455	600	3-9

### 25. Construction of a Radiating Loop.—

The construction of the loop for use in radiating a signal to the receiver is described in general terms because the material available won't be the same in all cases. Perhaps the simplest and quickest method of making the loop is to use a heavy piece of wire attached to a support. The main design features which should be retained if the loop is to be used for producing a field strength of known magnitude are the loop diameter and the value of the series-connected resistor, R. If, however, the loop is to serve merely as a means of introducing the signal to the receiver without direct electrical connection, even these design features may be overlooked. The arrangement shown in figure 26 illustrates one possible version that can be

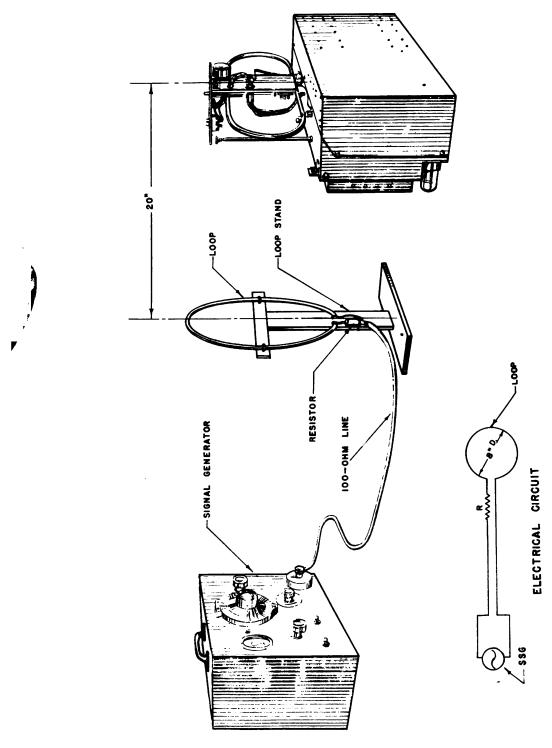

Figure 26. Test Set-up for a Radiating Loop

Generated on 2015-10-06 19:56 GMT / http://hdl.handle.net/2027/uc1.b3243879 Public Domain, Google-digitized / http://www.hathitrust.org/access\_use#pd-google

used. The loop in this case consists of a single turn of  $\frac{1}{4}$ " copper tubing supported by a non-metallic stand. The terminals of the loop are connected to the 100-ohm line of the signal generator through the series resistor, R. The loop when used at a distance of 20 inches from the receiver loop produces a field strength at the receiver which is 1/10 the signal generator output—that is, with a signal generator output of 1000 microvolts, the field strength is 100 microvolts per meter. The factor 1/10 and the other physical constants are calculated from the equation:

$$e = \frac{18.85 \text{ Nr}^2 \text{ I}}{\text{x}^3}$$
 (Eq. 1)

Where e = field strength at the receiving loop in microvolts per meter,

N = number of turns of radiating loop,

r = radius of transmitting loop in centimeters,

I = current through radiating loop in milliamperes,

x = distance between center of radiating and receiving loops in meters.

If the inductance of the loop is made low, so that the reactances of the loop (at the highest frequency it is desired to operate) is small compared to the value of the series resistor, then the current in the loop can be calculated very readily; thus the current is given by:

$$I = \frac{E}{1000 \text{ R}} \qquad (Eq. 2)$$

In which E is the signal generator output in microvolts and R is he value of the series resistor in ohms.

By substituting equation 2 in equation 1, the following expression s obtained:

$$e = \frac{18.85 \text{ Nr}^2 \text{ E}}{x^3 1000 \text{ R}}$$
 (Eq. 3)

If e is set equal to .1E then:

$$.1E = \frac{18.85 \text{ Nr}^2 \text{ E}}{x^3 1000 \text{ R}}$$
 (Eq. 4)

When equation 4 is solved for R, the following is obtained:

$$R = \frac{18.85 \text{ Nr}^2}{100 \text{ x}^3}$$
 (Eq. 5)

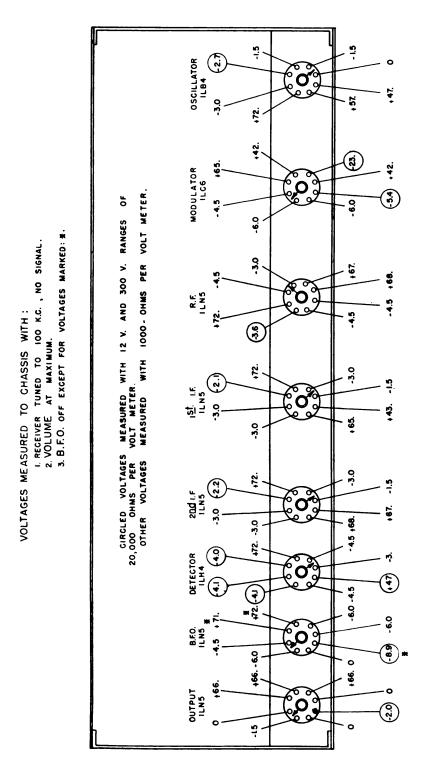

Figure 27. Radio Receiver BC-792-A, Diagram of Tube Sockets With Operating Voltages

For the present case we choose:

$$N = 1$$
  
 $r = 10$  cm.  $(4'')$   
 $x = .5$  m.  $(20'')$ 

Substituting these values in equation 5 gives:

$$R = 150 \text{ ohms}$$

There are several factors which impose limitations on the upper frequency limit at which a radiating loop of this type can be used to give known field strength. As the frequency approaches 20 mc. the reactance of the loop described becomes sufficiently large (approximately 50 ohms) so that the current no longer remains at the value determined by the resistor, R, at lower frequencies. Another source of error may be introduced by a resonant condition in the line from the signal generator. Further sources of error are caused by capacitive coupling from the loop to the receiver. Capacitive coupling to the receiver includes coupling to the receiver loop and to the leads connecting the output load box. However, despite all these effects which enter at higher frequencies, the loop is still a convenient means of coupling the signal generator to the receiver for purposes of alignment.

### 26. Voltage Measurements of Radio Receiver BC-792-A.

- a. A very useful means for finding the source of trouble in the receiver is to check the d-c voltages at the tube sockets. To make test points accessible it's necessary to remove the cover from the receiver. Before proceeding with the actual measurements, make sure that the A and B batteries are fully charged by testing them with the charger as described in paragraph 9. The control plate must be connected to the receiver with the connectors (123 and 125). Throw POWER switch to ON.
- b. The voltages that should be measured on a normal receiver are shown in figure 27. Because of the tolerance allowed on the values of various circuit elements, deviations of  $\pm 10\%$  from the normal are permissible.

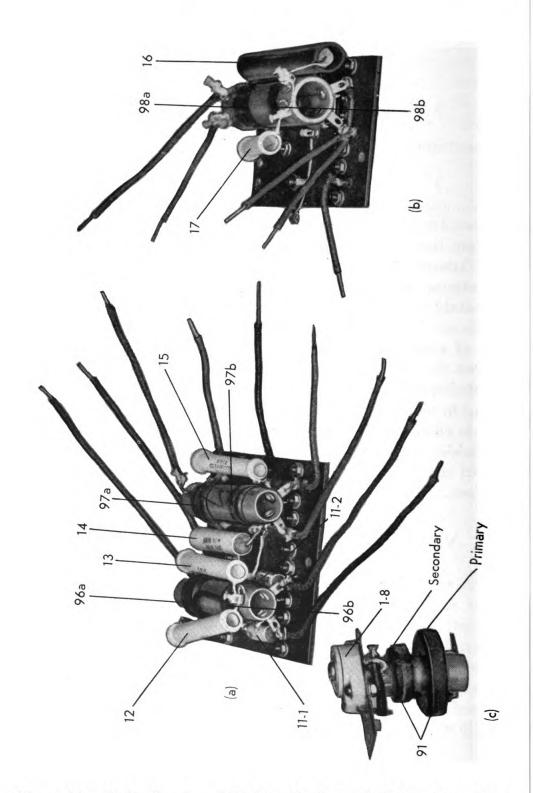

Figure 28. Radio Receiver BC-792-A, Oscillator Coil Sub-Assemblies, Typical R-F Coil Assembly

- c. To make the voltage measurements, connect one side of the voltmeter to any convenient part of the chassis, and then use a test prod connected to the other side of the voltmeter to contact the terminals of each of the sockets in turn. Be careful not to short-circuit any adjacent terminals on the tube sockets with the test prod. It's usually most convenient to measure all the positive voltages with respect to chassis, and then, by connecting the positive side of the voltmeter to the chassis, measure all the negative voltages. In general the voltages are measured with a 1000-ohm per volt meter. The exceptions are indicated in figure 27 by the circles around certain voltages measured in very high resistance circuits. In these instances the voltmeter used had a resistance of 20,000 ohms per volt, in order not to reduce excessively the voltage at the points measured. If you have only a 1000-ohm per volt meter available, the voltages you observe will be considerably lower at these points.
- d. In case any of the voltages measured are abnormally low, this information can be used to diagnose the source of the trouble. For example, if the plate voltage measured at any of the tube sockets is zero, the coil or resistor in that plate circuit should be investigated for an open circuit, or if the filament voltage is absent at one or more tubes, it's a positive indication that a tube is burned out. Always keep in mind that if one tube in a filament string burns out, the other tubes of that string are deprived of filament current. Another example of using the information given by measuring tube socket voltages is the case in which the screen voltage is also zero in addition to the zero plate voltage. A likely cause for this condition is a damaged screen by-pass capacitor or an open circuited isolation resistor.

### 27. Resistance Measurements of Radio Receiver BC-792-A.—

a. If all voltages are normal or the interpretation of any abnormalities doesn't lead to the trouble, further investigation should be carried on by measuring the continuity between various points and resistance to ground. The following table lists the nominal resistance measurable in a normal receiver. Resistance values greater than 5 megohms are tabulated as infinite. CAUTION: BEFORE MAKING POINT-TO-POINT RESISTANCE MEASUREMENTS THE

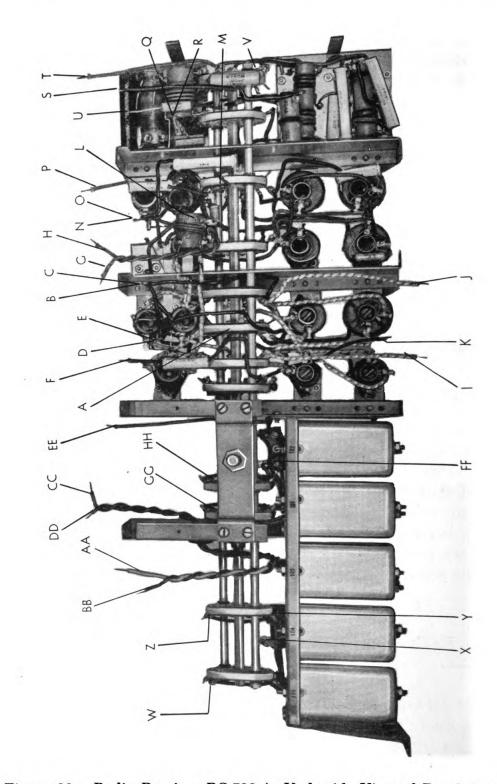

Figure 29. Radio Receiver BC-792-A, Underside View of Band Switch Assembly Showing Designations of Leads and Terminal Points

BATTERIES MUST BE REMOVED FROM THE RECEIVER; OTHERWISE INCORRECT READINGS WILL RESULT AND THE OHMMETER WILL BE DAMAGED. IMPORTANT: REMOVE BATTERIES.

### b. Table of Resistance Measurements From Tube Sockets To Ground

d. Since the measurement of each and every circuit in the reiver would require considerable time, make measurements accordg to the type of trouble at hand. For example, if the receiver is operative in only one band, all the coils which are used solely in at band should be tested for continuity. If, however, the receiver inoperative in bands 1, 3, 4, and 5, investigations should center ound the 455-kc i-f channel. The continuity of transformers 101,

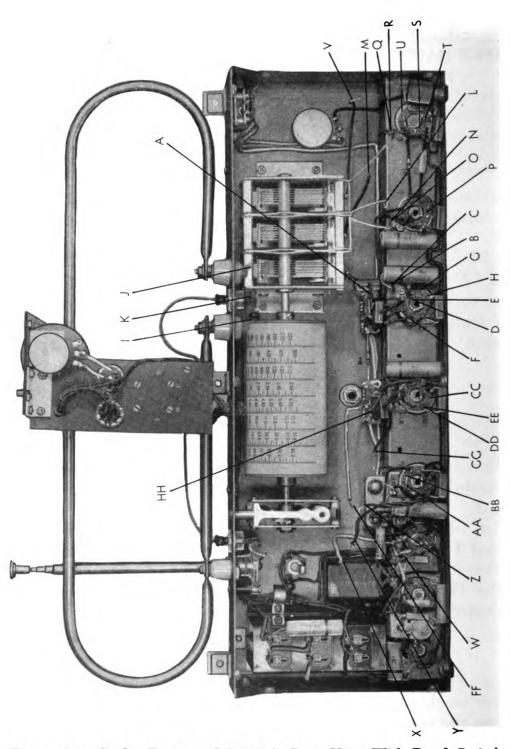

Figure 30. Radio Receiver BC-792-A, Rear View With Band Switch Assembly Removed From Chassis, Showing Designations of Leads and Terminal Points

103 should be checked. By the same token if only bands 2, 6, 7 and 8 are inoperative, the continuity of transformers 102, 104, 105 should be checked. If the receiver is inoperative on all bands, it's usually quicker to determine in which stage of the receiver the trouble is by using a signal generator. This technique will be explained in paragraph 28. The following table of Resistance Measurements gives the resistance of all inductors. The resistance measurements having values less than 1 ohm are tabulated as zero since for the purpose of trouble shooting it's not necessary to know the exact resistance.

### e. Table of Resistance Measurements of Inductors

### 28. Use of Signal Generator to Locate Trouble.—

If neither the voltage nor continuity measurements lead to the source of trouble in a completely inoperative receiver, the following procedure is recommended.

- a. Prepare the receiver as for normal operation; insert batteries, turn on POWER switch and connect an output meter and a headset.
- b. Advance the VOLUME control to maximum and connect a signal generator through a suitable coupling capacitor successively to the signal grids of the tubes.
- c. The order of doing this should start with the output tube in which case an audio frequency (400 cycles) is required from the signal generator. If no output is heard in the headset, the trouble is then known to be in the output tube or its associated circuit.
- d. If the output stage passes the signal, then proceed to the previous tube connecting the audio frequency generator to the signal grid of the detector (117).
- e. In like fashion, a signal generator supplying the correct intermediate frequency to the signal grids of tubes 118-3, 118-2 and 115 successively will reveal in which stage of the receiver the trouble exists.
- f. If the sensitivity at the modulator signal grid (pin 6) is normal (approximately 20 microvolts), then the sensitivity at the same grid should be checked using the r-f signal to which the receiver is tuned.
- g. The signal generator should then finally be coupled to the signal grid of the r-f tube in order to complete the step by step search for the source of trouble.

### 29. Replacement of Individual I-F, R-F and Antenna Transformers.—

a. If it becomes necessary to remove one of the transformers as a result of damage to either the coils or the associated trimmer, in general this may be done without resorting to a major dismemberment.

### b. I-F Transformers.—

The i-f transformers can be removed by unsoldering the leads from the switch and other terminals. After the two nuts on the spade bolts are taken off, the i-f transformer complete with can should be gently removed from the metal channel.

### c. Antenna Transformers.—

In removing the antenna transformers unsolder the leads from the band switch at the transformer terminals rather than at the switch. Each antenna transformer of bands 1 to 7 is fastened to the top of the switch partition by a single screw. Band 8 antenna transformer is fastened by a single screw to the side of a switch partition and is located near the modulator tube. To facilitate removing its fastening screw, a hole has been provided in the partition between the oscillator and modulator tubes so that a long, thin screw driver may be inserted from the oscillator end of the receiver.

### d. R-F Transformers.—

All the r-f transformers can be detached by means of the single fastening screw and by disconnecting the leads at the transformer terminals. A typical r-f transformer assembly is shown in figure 28(c). The terminals at the trimmer end of the transformer belong to the secondary circuit and those at the other end belong to the primary circuit.

### e. Oscillator Transformers.—

- (1) If one of the oscillator transformers of bands 1 to 4 has to be removed, this can be accomplished only by removing the entire sub-assembly on which these are mounted. This sub-assembly is shown in figure 28(a).
- (2) The most convenient way to remove this sub-assembly is to unsolder the leads going to switch wafers K and L. A total of 8 leads on the latter wafers must be unsoldered. In addition, the black lead going to the solder lug on the five-trimmer plate must be unsoldered at the lug. The eight-trimmer plate assembly can then be removed by taking out three screws of which two are in the switch shield partition and one in the support bracket. When this sub-assembly has been removed, all the necessary soldered joints are accessible for removing any defective components.

- (3) If band 5 or band 6 oscillator transformers must be removed, it is necessary in like fashion to remove the sub-assembly from the receiver. This sub-assembly is shown in figure 28(b). To accomplish this operation, the leads going to wafers K and L of the band switch should be unsoldered.
- (4) Band 7-8 oscillator transformer is held to the switch partition by a single screw. It can be removed without disconnecting any leads other than those connecting to it.

### 30. Removal of Band Switch Assembly From Radio Receiver BC-792-A.—

- a. If some defect occurs in the receiver which can't be remedied because it's inaccessible, you can remove the entire switch assembly and get at the part you want to fix. SINCE THIS OPERATION IS QUITE COMPLICATED AND TIME CONSUMING, IT MUST NOT BE UNDERTAKEN UNLESS IT HAS BEEN DEFINITELY ESTABLISHED THAT THE DIFFICULTY CANNOT BE REMEDIED WITHOUT REMOVING THE ASSEMBLY. BEFORE ATTEMPTING TO REMOVE THE SWITCH ASSEMBLY, TAKE CARE OF THE FOLLOWING:
  - (1) Remove all batteries.
- (2) Set tuning control to low frequency end of dial (if this is not done, the tuning capacitor plates may become bent in the following work).
- (3) Disconnect the control head completely by removing the connectors and plugs.
- b. Figure 29 shows the switch assembly removed from the receiver. Figure 30 shows the receiver chassis after the switch assembly has been removed. Note that in each figure certain leads remain with each unit. In disconnecting the leads at their terminals, make certain that they remain with the units exactly as shown in these two figures. To identify the leads and their respective connecting terminals they have been designated with the same reference letter. Since there are 34 connections, the designations go from A to Z and from AA to HH. There is no significance attached to the use of the double letter designations beyond that necessary to distinguish them from the single letter. After all 34 junctions have been unsoldered, remove the screws fastening the switch partitions to the chassis. There's a

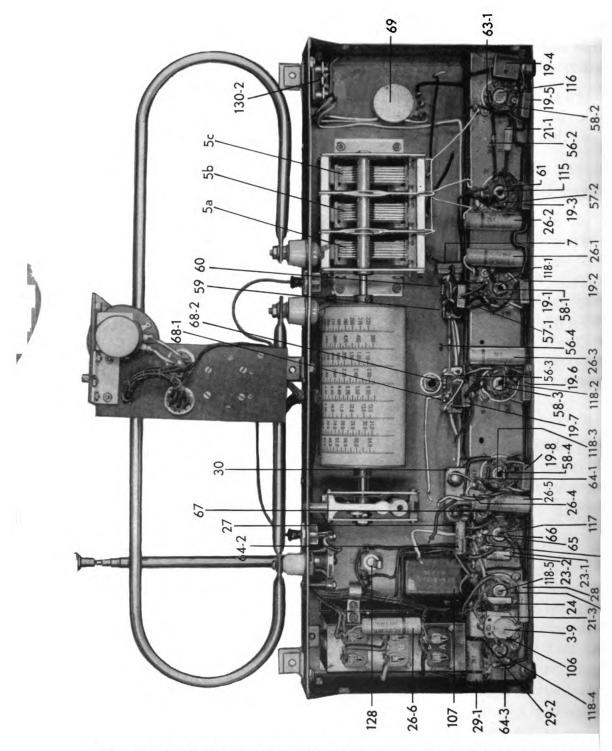

Figure 32. Radio Receiver BC-792-A, Rear View With Band Switch Assembly Removed From Chassis, Showing Reference Numbers of Parts

total of 13 screws to be removed before the switch assembly is mechanically free. Then remove the BAND SWITCH knob from its shaft. Very carefully pull the switch assembly out of the receiver by grasping it at the central partitions. It will come out without the application of much force. If it tends to bind or catch, look for the cause before anything is damaged by excessive strain.

Figure 31 shows the switch assembly with all its components referenced according to the numbers given in the List of Replaceable Parts. The components in the chassis assembly are similarly shown in figure 32.

### 31. Trouble Shooting for Battery Charger PE-128-A.—

- a. If you find trouble in the use of the charger, all the items in paragraph 23 should be thoroughly checked. If you can't fix the charger by using the remedies prescribed in this chart, the source of the trouble should be investigated through voltage and resistance measurements. Remove the ten screws holding the bottom plate of the charger so that the circuits are accessible. (See figure 33.)
- b. The panel voltmeter (143) reading obtained when no batteries are in the circuit serves to indicate the presence of voltage in the "A" portion of the charger. If this voltage is low or entirely absent, an external voltmeter should be connected successively to the terminals of capacitor (37 a and b), and to the terminals of fuse (138). The presence or absence of voltage at these various points will indicate which circuit element is damaged. When there are no "B" batteries inserted in the charger, the panel voltmeter (143) does not indicate the charger voltage developed in the "B" portion. The voltage between the common negative of capacitor (36), and the terminals of fuse (139), and the terminals of control (76) should indicate the circuit element at fault. The normal voltage (with 6-volt supply) should be approximately 150 volts at the junction of the capacitor (36a) and fuse (139). If no load is connected, the same voltage will be measured at the terminals of control (76).
- c. In the event that the voltage measured is abnormally low, capacitors (34, 36 a & b and 37 a & b) should be checked for breakdown. The resistance of the windings on transformer (111) are given

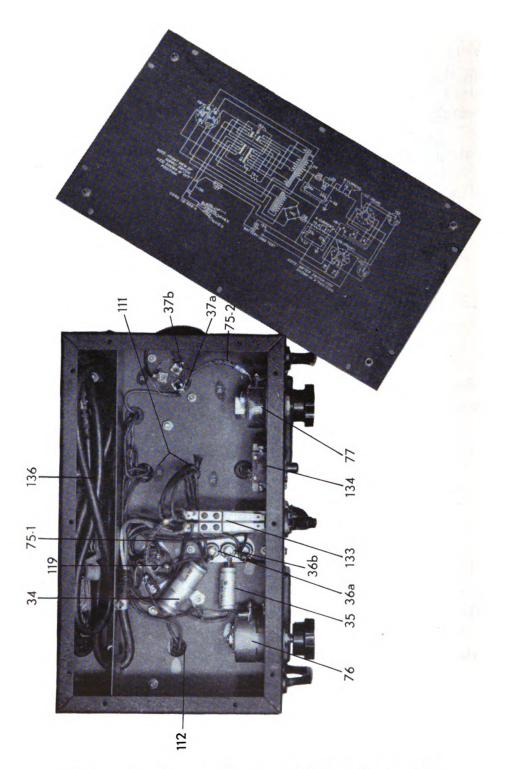

Figure 33. Battery Charger PE-128-A, Bottom View With Bottom Plate Removed

in the following table. You must make these measurements with the SUPPLY switch in the OFF position. The continuity of the energizing coil on the vibrator can be checked by connecting the ohmmeter to terminals 3 and 6 of socket of vibrator (119). Switch (134) should be checked for continuity between the terminals connected to the black leads. The terminals connected to the green leads normally should show an open circuit. When the button of the BATTERY LOAD TEST is pushed, the black lead terminals should show open circuit and the green lead terminals short circuit.

### d. Table of Resistance Measurements on Charger PE-128-A

(1) Winding	Color Code	Resistance Ohms
Primary	BK-OR to YL-BU	0.4
Primary	WH to YL-BK	0.4
Primary	YL-BK to BK	0.4
Primary	GR-WH to GR	0.4
Secondary	RD-GR to RD-YL	210.
Secondary	RD-YL to RD	220.
Secondary	BU to BU	2.
Choke (112)	RD to RD	1000.
(2) Winding	Where Measured	Resistance Ohms
Vibrator Energizing Coil	Pins 3 and 6 of (119)	11.
B Control (76) HIGH position	Terminals to red leads	0.
B Control (76) LOW position	Terminals to red leads	10,000.
A Control (77) HIGH position	Blue lead terminal to center.	0.
A Control (77) LOW position	Blue lead terminal to center.	450.

NOTE: The common negative of the charger circuit is not connected to the chassis and therefore no connection should be made to chassis when making voltage and resistance measurements.

### 32. General Maintenance of Battery Charger PE-128-A.—

Since the charger is subjected to the corrosive action of the acid from the batteries, a periodic inspection and cleaning is recommended. The battery compartment should be thoroughly cleansed of all accumulations of dirt and acid so that corrosion will be minimized. The pin jacks in the rear of the battery compartment should be examined and cleaned, if necessary, to prevent corrosion. The battery clips on Cord CD-658-A should be inspected and cleaned frequently. The leads attached to the clips should also be examined for breakage and loose connections.

### SECTION V SUPPLEMENTARY DATA

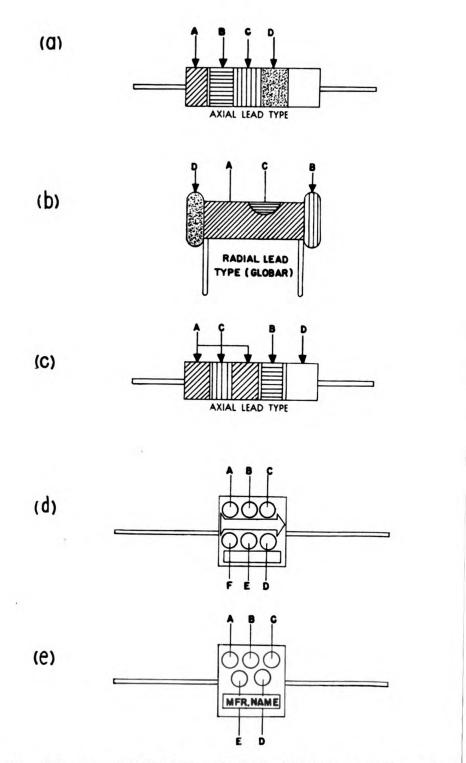

Figure 35. Diagram of RMA Color Code for Resistors and Capacitors

Generated on 2015-10-08 01:29 GMT / http://hdl.handle.net/2027/uc1.b3243879 Public Domain, Google-digitized / http://www.hathitrust.org/access\_use#pd-google

- \*Note: Use of the colors Green and Blue in place of Gold and Silver is optional in order to avoid use of strategic materials and effect of metallic content paints.
- a. Resistors.—The nominal resistance value of fixed carbon resistors is indicated in three manners. The colors used to represent the resistance values in ohms are given in the above table. The system in most common use for axial lead resistors indicates the value with colored bands as in figure 35(a), in which:
- (1) Band A indicates the first significant figure of the resistance value.
  - (2) Band B indicates the second significant figure.
  - (3) Band C indicates the multiplier.
- (4) Band D, if any, indicates the tolerance limits about the nominal resistance value. No tolerance color indicates 20 percent.

For radial lead resistors (such as Globar) the system shown in figure 35 (b) is used, in which the colors of—

- (1) The body (A) indicates the first significant figure of the resistance value.
  - (2) One end (B) indicates the second significant figure.
  - (3) A dot (C) indicates the multiplier.
- (4) The other end (D) indicates the tolerance limits about the nominal resistance value. No tolerance color indicates 20 percent.

A system, not too commonly used at present, for indicating nominal resistance value of axial lead resistors is shown in figure 35 (c) in which the colors of:

- (1) The body (A) indicates the first significant figure of the resistance value.
  - (2) A band (B) indicates the second significant figure.
  - (3) A band or dot (C) indicates the multiplier.
- (4) Band (D) if any, indicates the tolerance limits about the nominal resistance value. No tolerance color indicates 20 percent.
- b. Capacitors.—Two systems for color coding fixed mica capacitors are in use. The colors used to represent the capacitance value, in micro-microfarads, are given in the table at the beginning of this paragraph. Note that the colored dots are read from left to right in the direction indicated by the molded arrow, or in the same direction as the manufacturer's name.

A system now in common use involves six dots of color as in figure 35 (d) in which the color of:

- (1) Dot A indicates the first significant figure of the capacitance value.
  - (2) Dot B indicates the second significant figure.
  - (3) Dot C indicates the third significant figure.
  - (4) Dot D indicates the multiplier.
- (5) Dot E indicates the tolerance of the nominal capacitance value.
  - (6) Dot F indicates the voltage rating.

Another commonly used system involves the use of three dots of color which is interpreted in the same manner as the first part of the five-dot system shown in figure 35 (e). The latter is described because a number of mica capacitors used in Radio Receiver BC-792-A are thus coded. In figure 35 (e) the color of:

- (1) Dot A indicates the first significant figure of the capacitance value.
  - (2) Dot B indicates the second significant figure.
  - (3) Dot C indicates the multiplier.
  - (4) Dot D indicates the tolerance of the nominal capacitance.
  - (5) Dot E indicates the voltage rating.
